# 1 Introduction

This document describes the API (Application Programming Interface) and architecture of a system called SKS (Secure Key Store). SKS is essentially an enhanced smart card that is optimized for *secure, reliable, and user-friendly on-line provisioning and life-cycle management* of cryptographic keys and associated attributes.

In addition to PKI and symmetric keys (including OTP applications), SKS also supports recent additions to the credential family tree like [Information Cards](#).

The primary objective with SKS and the related specifications is *establishing two-factor authentication as a viable alternative for any provider* by making the scheme a standard feature in the “Universal Client”, the Internet browser.

An equally important means for reaching this undeniable bold goal, is that the API and protocols mandate full “on-the-wire” compliance in order to eliminate the current “Smart Card Middleware Hell”; *a single driver per platform should suffice*.

Could *existing* smart card users also benefit from an upgraded token technology? Yes, the new ways of working, like *virtual organizations*, doesn't make the current distribution scheme “Come and get your card” particularly useful.

For maintaining a link to the world of legacy authentication an SKS may also serve as a “Password Vault”.

## 2 Core Functionality

### 2.1 Architecture

Below is a picture showing the core components in the SKS architecture:

The *Device Certificate* forms together with a matching *Attestation Private Key* the foundation for the session mechanism that facilitates secure provisioning of keys, also when the provisioning middleware and network are non-secure.

The *Credential Database* holds keys and other data that is related to keys such as protection and extension objects. It also keeps the provisioning state.

The *Cryptographic Engine* performs in addition to standard cryptographic operations on private and secret keys, the core of the provisioning operations which from an API point-of-view are considerably more complex than the former.

A vital part of the *Cryptographic Engine* is a high quality random number generator since the integrity of the entire provisioning scheme is relying on this.

All operations inside of an SKS are supposed to be protected from tampering by malicious external entities but the degree of *internal* protection may vary depending on the environment that the SKS is running in. That is, an SKS housed in a smart card which may be inserted in an arbitrary computer must keep all data within its protected memory, while an SKS that is an integral part of a mobile phone processor *may* store credential data in the same external Flash memory where programs are stored, but sealed by a CPU-resident “Master Key”.

### 2.2 Provisioning API

Although SKS may be regarded as a “component”, it actually comprises of three associated pieces: The [KeyGen2](#) protocol, the SKS architecture, and the provisioning API described in this document. These items are *tightly matched* which is more or less a prerequisite for *large-scale, secure and interoperable* ecosystems of cryptographic keys. Also see [KeyGen2 Proxy](#).

One of the core features of the SKS Provisioning API is enabling independent issuers securely *sharing* a single “Key Ring”. The rationale for this is mainly to support mobile phones with embedded “Trusted Hardware”, but it appears that the already quite popular USB memory sticks augmented with SKS functionality would be a realistic product offering if they could deal with a potentially large chunk of a consumer's authentication hassles on the Internet.

## 2.3 User API

In this document “User API” refers to operations that are required by security applications like [TLS](#) client-certificate authentication, [S/MIME](#), and [Kerberos](#) (PKINIT).

The User API is not a core SKS facility but its implementation is anyway **recommended**, particularly for SKSes that are featured in “connected” containers such as smart cards since smart card middleware has proved to be a major stumbling block for wide-spread adoption of PKI cards for consumers.

The described User API is fully mappable to the subset of [CryptoAPI](#), [PKCS #11](#), and [JCE](#) that the majority of current PKI-using applications rely on.

The standard User API does not utilize authenticated sessions like featured in [TPM 1.2](#) because this is a *local security option*, which is independent of the *network centric* [Provisioning API](#).

If another User API is used the only requirement is that the key objects created by the provisioning API, are compatible with the former.

## 2.4 Security Model

Since the primary target for SKS is authentication to arbitrary service providers on the Internet, the security model is quite different to traditional multi-application card schemes like [GlobalPlatform](#). In practical terms this means that it is the *user* who grants an issuer the right to create keys in the SKS. That is, there are no preconfigured “Security Domains”.

However, an issuer may during a provisioning session define a VSD (Virtual Security Domain) which enables *post provisioning (update) operations* by the issuer, while cryptographically shielding provisioned data from similar actions by *other* issuers.

When using [KeyGen2](#) the grant operation is performed through a GUI dialog triggered by an issuer request, which in turn is the result of the user browsing to an issuer-related web address.

The SKS itself only trusts inbound data that can securely be derived from a session key created in the initial phase of a provisioning session. See [createProvisioningSession](#).

The session key scheme is conceptually similar to [GlobalPlatform](#)'s SCP (Secure Channel Protocol) but details differ because [KeyGen2](#) uses an on-the-wire XML format requiring encoding/decoding by the middleware, rather than raw APDUs.

Regarding who trusts an SKS, this is effectively up to each issuer to decide and may be established anytime during an enrollment procedure. Trust in an SKS can be highly granular like only accepting requests from preregistered units or be fully open ended where any SKS compliant device is accepted. A potentially useful issuer policy would be specifying a set of endorsed SKS brands, presumably meeting some generally recognized certification level like EAL5.

Many smart card schemes depend on roles like SO (Security Officer) which squarely matches scenarios where users are associated with a *multitude of independent service providers*. By building on an E2ES (End To End Security) model, the *technical* part of the SO role, exclusively becomes an affair between the SKS and the *remote* issuers, *where each issuer is confined to their own virtual cards and SO policies*.

Also see [Security Considerations](#) and [Privacy Enabled Provisioning](#).

## 2.5 Transaction Based Operation

An important characteristic for maintaining integrity and robustness is that provisioning and management operations either succeed or leave the system intact. This is accomplished by *deferring* the actual “commit” of container-modifying operations until the terminating [closeProvisioningSession](#) call.

Ideally an SKS container should be able dealing with power-failures regardless when they occur.

## 2.6 Privacy Enabled Provisioning

Note: Credential *provisioning* and credential *usage* (at least when the issuer is independent of the relying party), *represent two entirely different scenarios from a privacy point of view*.

Although a one-size-fits-all approach would be nice, it seems that the span of Internet-related services motivates a design that supports on-line identity schemes where issuers have (often quite substantial) knowledge about users, as well as close to fully anonymous relationships.

The “Standard” E2ES (End To End Security) mode which exploits the SKS [Device Certificate](#) and [Attestation Private Key](#) in the provisioning API, is intended to suit the needs of banks, employers, governments, and high-security third-party identity providers.

The PEP (Privacy Enabled Provisioning) mode is identical to the E2ES mode, with the exception that the identity of the SKS is excluded. A valid question is if the PEP mode is equally secure as the E2ES mode. The simple answer to that is a clear “No”, since the issuer neither learns the type (=quality, brand), nor the identity of the SKS.

However, from a *user's horizon* the PEP mode is as secure and trustworthy as the E2ES mode as long as the client platform is intact and the correct issuer enrollment URL is used. After provisioning there are no security differences whatsoever between the two modes.

From a purely technical perspective, [Blind Signatures](#) or elaborate schemes like TCG's [DAA](#) (Direct Anonymous Attestation) could also have been applied. Adoption considerations for a mode primarily intended replacing passwords were governing the decision keeping things simple.

The PEP mode is selected by the [PrivacyEnabled](#) parameter of [createProvisioningSession](#).

## 2.7 Device ID

Since the exposed identity of the SKS container is dependent on the mode as described in the previous section, the affected provisioning methods refer to a “Device ID” which is the literal string “**Anonymous**” and the binary form of [Device Certificate](#) for the [Privacy Enabled Provisioning](#) and [E2ES](#) mode respectively.

## 2.8 Backward Compatibility

A question that arises is of course how compatible the SKS [Provisioning API](#) is with respect to existing protocols, APIs, and smart cards. The answer is simply: NOT AT ALL due to the fact that current schemes do *generally* not support secure on-line provisioning and key life-cycle management directly towards end-users.

In fact, *smart cards are almost exclusively personalized by more or less proprietary software under the supervision of card administrators or performed in automated production facilities*. It is evident that (at least) mobile phones need a scheme that is more consistent with the on-line paradigm since SIM-cards due to operator-bindings do not scale particularly well.

*“On the Internet anybody can be an operator of something”*

Note: unlike 7816-compatible smart cards, an SKS exposes no visible file system, only objects.

Although the lack of compatibility with the current state-of-the-art (“nothing”), may be regarded as a major short-coming, the good news is that SKS by separating key provisioning from actual usage, *does neither require applications nor cryptographic APIs to be rewritten*.

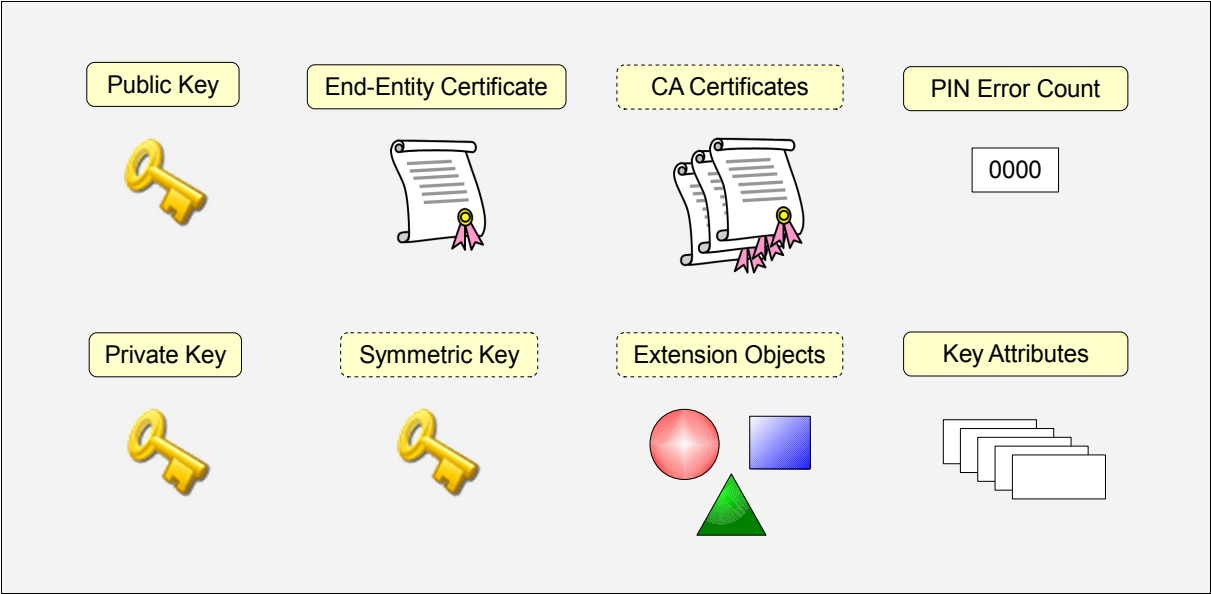

# 3 Objects

The SKS API (as well as its companion protocol [KeyGen2](#)), assumes that objects are arranged in a specific fashion in order to work. At the heart of the system there are the typical cryptographic keys intended for user authentication, signing etc., but also dedicated keys supporting life-cycle management and of user keys and attributes.

All provisioned user keys, including symmetric dittos (see [importSymmetricKey](#)), are identified by [X.509](#) certificates. The reason for this somewhat unusual arrangement is that this enables *universal key IDs* as well as *secure remote object management by independent issuers*. See [Remote Key Lookup](#).

## 3.1 Key Entries

The following picture shows the elements forming an SKS key entry:

Element	Description
Public Key	Public part of the asymmetric key-pair created by <a href="#">createKeyEntry</a>
Private Key	Private part of the asymmetric key-pair created by <a href="#">createKeyEntry</a>
End-Entity Certificate	<a href="#">X.509</a> certificate set by the <i>mandatory</i> call to <a href="#">setCertificatePath</a>
Symmetric Key	<i>Optional</i> symmetric key defined by calling <a href="#">importSymmetricKey</a>
CA Certificates	<i>Optional</i> <a href="#">X.509</a> CA certificates defined during the call to <a href="#">setCertificatePath</a>
Extension Objects	<i>Optional</i> extension objects defined by calling <a href="#">addExtension</a>
PIN Error Count	Counter associated by keys protected by a PIN policy object. See <a href="#">createPINPolicy</a>
Key Attributes	Attributes defined during the call to <a href="#">createKeyEntry</a>

Note that key management operations always involve an entire key entry; *individual elements cannot be managed*.

## 3.2 Key Protection Objects

Keys can *optionally* be protected by PIN-codes (“passphrases”). PIN-protected keys maintain separate PIN error counters, but a single PIN policy object may govern multiple keys. A PIN policy and its associated keys can in turn be supplemented by an optional PUK (PIN Unlock Key) policy object that can be used to reset error-counters that have passed the limit as defined by the PIN policy. Below is an illustration of the SKS protection object hierarchy:

For the creation of protection objects, see [createPUKPolicy](#), [createPINPolicy](#) and [createKeyEntry](#).

For an example how [KeyGen2](#) deals with this structure, see [KeyCreationRequest](#).

Note that the set of keys bound to a particular PIN policy object “owns” the PIN policy object which means that when the *last* key of such a set has been deleted, the PIN policy object itself **must** be *automatically* deleted (by [pp\\_deleteKey](#) and [deleteKey](#)). The very same principle is also valid for PUK policy objects. Due to this there are no specific PIN or PUK delete methods.

An *embedded* SKS **may** also support a device (system-wide) PIN and PUK. See [getDeviceInfo](#). *Usage and management of device PINs and PUKs is out of scope for the SKS API.*

## 3.3 Provisioning Objects

The following picture shows how provisioning objects “own” the keys they have provisioned:

For detailed information concerning the contents of a provisioning object see [createProvisioningSession](#).

Note that when the *last* key owned by a provisioning object has been deleted, the provisioning object itself **must** be *automatically* deleted (by [closeProvisioningSession](#) and [deleteKey](#)).

If a [KeyManagementKey](#) is deployed during provisioning object creation (establishing a [VSD](#)), *post-provisioning operations* can also be performed. See [pp\\_deleteKey](#), [pp\\_unlockKey](#), [pp\\_updateKey](#), and [pp\\_cloneKeyProtection](#).

## 4 Algorithm Support

Algorithm support in SKS **must** as a *minimum* include the following items:

URI	Description
-----	-------------

Symmetric Key Encryption	
<a href="http://www.w3.org/2001/04/xmlenc#aes128-cbc">http://www.w3.org/2001/04/xmlenc#aes128-cbc</a>	See <a href="#">XML Encryption</a> . Note that <b>IV</b> <b>must</b> be <i>internally generated</i> as well as <i>prepended</i> to encrypted data
<a href="http://www.w3.org/2001/04/xmlenc#aes192-cbc">http://www.w3.org/2001/04/xmlenc#aes192-cbc</a>	
<a href="http://www.w3.org/2001/04/xmlenc#aes256-cbc">http://www.w3.org/2001/04/xmlenc#aes256-cbc</a>	
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.aes.cbc.pkcs5">http://xmlns.webpki.org/keygen2/1.0#algorithm.aes.cbc.pkcs5</a>	See <a href="#">FIPS 197</a> . Support for 128, 192, and 256-bit keys
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.aes.ecb.nopad">http://xmlns.webpki.org/keygen2/1.0#algorithm.aes.ecb.nopad</a>	

HMAC Operations		
<a href="http://www.w3.org/2000/09/xmlsig#hmac-sha1">http://www.w3.org/2000/09/xmlsig#hmac-sha1</a>	See <a href="#">HMAC-SHA1</a>	
<a href="http://www.w3.org/2001/04/xmlsig-more#hmac-sha256">http://www.w3.org/2001/04/xmlsig-more#hmac-sha256</a>	See <a href="#">HMAC-SHA256</a>	

Asymmetric Key Encryption		
<a href="http://www.w3.org/2001/04/xmlenc#rsa-1_5">http://www.w3.org/2001/04/xmlenc#rsa-1_5</a>	See <a href="#">XML Encryption</a>	<i>Decryption mode only</i>
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.rsa.raw">http://xmlns.webpki.org/keygen2/1.0#algorithm.rsa.raw</a>	Non-padded RSA operation	

Diffie-Hellman Key Agreement		
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.ecdh.raw">http://xmlns.webpki.org/keygen2/1.0#algorithm.ecdh.raw</a>	See <a href="#">SP800-56A</a> ECC CDH primitive (Section 5.7.1.2)	

Asymmetric Key Signatures		
<a href="http://www.w3.org/2000/09/xmlsig#rsa-sha1">http://www.w3.org/2000/09/xmlsig#rsa-sha1</a>	See <a href="#">XML Signature</a>	<i>Signing mode only</i>
<a href="http://www.w3.org/2001/04/xmlsig-more#rsa-sha256">http://www.w3.org/2001/04/xmlsig-more#rsa-sha256</a>		
<a href="http://www.w3.org/2001/04/xmlsig-more#ecdsa-sha256">http://www.w3.org/2001/04/xmlsig-more#ecdsa-sha256</a>		
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.rsa.none">http://xmlns.webpki.org/keygen2/1.0#algorithm.rsa.none</a>	See <a href="#">signHashedData</a>	
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.ecdsa.none">http://xmlns.webpki.org/keygen2/1.0#algorithm.ecdsa.none</a>		

Elliptic Curves		
<a href="urn:oid:1.2.840.10045.3.1.7">urn:oid:1.2.840.10045.3.1.7</a>	Also known as “P-256”. See <a href="#">FIPS 186-3</a>	

Special Algorithms		
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.s1">http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.s1</a>	See <a href="#">createProvisioningSession</a>	
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.k1">http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.k1</a>	See <a href="#">createKeyEntry</a>	
<a href="http://xmlns.webpki.org/keygen2/1.0#algorithm.none">http://xmlns.webpki.org/keygen2/1.0#algorithm.none</a>	See <a href="#">createKeyEntry</a> and <a href="#">importSymmetricKey</a>	

Supported algorithms can be acquired by calling [getDeviceInfo](#) which also lists RSA key generation capabilities which **must** include 1024 and 2048 bit keys.

## 5 Key Protection Attributes

The following section describes the attributes issuers need to set for defining suitable key protection policies. Also see [getKeyProtectionInfo](#), [KeyManagementKey](#), [DevicePINProtection](#), and [EnablePINCaching](#).

During provisioning of *user defined PINs*, the provisioning middleware **should** maintain the PIN policy and optionally ask the user to create another PIN if there is a policy mismatch because [createKeyEntry](#) **must** return an error and abort the entire session if fed with incorrect data. Also see [KeyGen2 Proxy](#).

In addition to protection policies, a key **may** also be constrained with respect to algorithm usage. See [EndorsedAlgorithms](#).

### 5.1 Key Export

The following table illustrates the use of the [ExportProtection](#) attribute:

KeyGen2 Name	Value	Description
<b>none</b>	0x00	No authorization needed for exporting the key
<b>pin</b>	0x01	Correct PIN is required
<b>puk</b>	0x02	Correct PUK is required
<b>non-exportable</b>	0x03	The key <b>must not</b> be exported

Also see [exportKey](#).

### 5.2 Key Delete

The following table illustrates the use of the [DeleteProtection](#) attribute:

KeyGen2 Name	Value	Description
<b>none</b>	0x00	No delete restrictions apply
<b>pin</b>	0x01	Correct PIN is required
<b>puk</b>	0x02	Correct PUK is required
<b>non-deletable</b>	0x03	The key <b>must not</b> be deleted

Also see [deleteKey](#).

## 5.3 PIN Input Methods

The [InputMethod](#) policy attribute tells how PINs **should** be inputted to the SKS according to the following table:

KeyGen2 Name	Value	Description
<b>programmatic</b>	0x01	PINs <b>should</b> only be given through the SKS User API
<b>trusted-gui</b>	0x02	Keys <b>should</b> only be used through a trusted GUI that does the actual PIN request and API invocation
<b>any</b>	0x03	No restrictions

Note that this policy attribute requires that the middleware is “cooperative” to be enforced.

## 5.4 PIN Patterns

The [PatternRestrictions](#) policy attribute specifies how PINs **must** be designed according to the following table:

KeyGen2 Name	Value	Description
<b>two-in-a-row</b>	0x01	Flags 1124 as <i>invalid</i>
<b>three-in-a-row</b>	0x02	Flags 1114 as <i>invalid</i>
<b>sequence</b>	0x04	Flags 1234, 9876, etc as <i>invalid</i>
<b>repeated</b>	0x08	All PIN bytes <b>must</b> be <i>unique</i>
<b>missing-group</b>	0x10	The PIN format <b>must</b> be <b>alphanumeric</b> or <b>string</b> and contain a mix of <i>letters</i> and <i>digits</i> . The <b>string</b> format also requires <i>lowercase</i> letters and <i>non-alphanumeric</i> characters. See <a href="#">PIN and PUK Formats</a>

Note that the [PatternRestrictions](#) byte actually holds a *set of bits*. That is, 0x00 means that there are no pattern restrictions, while 0x06 imposes two constraints. Also note that pattern policy checking is supposed to be applied at the *binary* level which has implications for the binary PIN format (see [PIN and PUK Formats](#)).

For organizations having very strict or unusual requirements on PIN patterns, it is **recommended** letting the user define PINs during enrollment in a web application and then deploy issuer-set PIN codes during provisioning.

## 5.5 PIN and PUK Formats

PINs and PUKs **must** adhere to one of formats described in the following table:

KeyGen2 Name	Value	Description
<b>numeric</b>	0x00	0 - 9
<b>alphanumeric</b>	0x01	0 - 9, A - Z
<b>string</b>	0x02	Any valid <a href="#">UTF-8</a> string
<b>binary</b>	0x03	Binary value, typically expressed as hexadecimal data

Note that format specifiers only deal with how PINs and PUKs are treated in GUIs; internally and in the SKS API, key protection data **must** always be handled as *decoded* strings of bytes. A conforming SKS **must** perform syntax validation during [createKeyEntry](#) on **numeric** and **alphanumeric** PIN data. Length of the clear-text binary value **must not** exceed 128 bytes. See **Format** attribute in [createPINPolicy](#) and [createPUKPolicy](#).

## 5.6 PIN Grouping

A PIN policy object may govern multiple keys. The [Grouping](#) policy attribute (which is intimately linked to the [Key Application Usage](#) scheme), controls how PINs to the different keys relate to each other according to the following table:

KeyGen2 Name	Value	Description
<b>none</b>	0x00	No restrictions
<b>shared</b>	0x01	All keys share the <i>same</i> PIN ( <i>synchronized</i> )
<b>signature+standard</b>	0x02	Keys with <a href="#">AppUsage</a> = <b>signature</b> share a common PIN while all other keys share <i>another</i> PIN ( <i>synchronized</i> )
<b>unique</b>	0x03	All four <a href="#">AppUsage</a> types must have <i>different</i> PINs while keys with the same <a href="#">AppUsage</a> share a common PIN ( <i>synchronized</i> )

Note that keys having a **shared** PIN grouping attribute **must** be treated as having a single virtual PIN error counter, while **signature+standard** implies two separate error counters. “Synchronized” means that a PIN *value* or *status* change **must** propagate to all keys sharing the PIN.

## 5.7 Key Application Usage

The [AppUsage](#) attribute specifies what *applications* keys are intended for according to the following table:

KeyGen2 Name	Value	Description
<b>signature</b>	0x00	The key <b>should</b> only be used in signature applications like <a href="#">S/MIME</a>
<b>authentication</b>	0x01	The key <b>should</b> only be used in applications like <a href="#">TLS</a> client certificate authentication and login to AD (Active Directory)
<b>encryption</b>	0x02	The key <b>should</b> only be used in encryption applications
<b>universal</b>	0x03	There are no restrictions on key usage

Enforcement of [AppUsage](#) is up to each *application* to perform.

Note that [AppUsage](#) **must not** constrain a key's *internal* use of cryptographic algorithms in any way, because for that purpose there is the [EndorsedAlgorithm](#) mechanism.

Although [AppUsage](#) could be regarded as a duplication of the [X.509](#) key usage and extended key usage attributes the latter have proved hard to use as “filters” to certificate selection GUIs. [AppUsage](#) is also applicable for other credentials like OTPs (One Time Passwords) and [Information Cards](#).

However, an equally important target for [AppUsage](#) is that in conjunction with [PIN Grouping](#) provide the means for aiding users in PIN input GUIs in the case an issuer requires separate PINs for different keys and applications.

The following matrix shows the **recommended** interpretation of PIN GUI “hints”:

PIN Grouping	<b>signature</b>	<b>authentication</b>	<b>encryption</b>	<b>universal</b>
<b>none</b>	PIN	PIN	PIN	PIN
<b>shared</b>	PIN	PIN	PIN	PIN
<b>signature+standard</b>	Signature PIN	PIN	PIN	PIN
<b>unique</b>	Signature PIN	Authentication PIN	Encryption PIN	PIN

For this scheme to work a prerequisite is (of course) that the middleware is specifically adapted for SKS.

## 5.8 Biometric Protection

An SKS **may** also support using biometric data as an alternative to PINs. See [getDeviceInfo](#). The following table shows the biometric protection options as defined by the [BiometricProtection](#) policy attribute:

KeyGen2 Name	Value	Description
<b>none</b>	0x00	No biometric protection
<b>alternative</b>	0x01	The key may be authorized with a PIN <i>or</i> by biometrics
<b>combined</b>	0x02	The key is protected by a PIN <i>and</i> by biometrics
<b>exclusive</b>	0x03	The key is <i>only</i> protected by biometrics

Note that there is no API support for biometric authentication, such information is typically provided through GPIO (General Purpose Input Output) ports between the biometric sensor and the SKS. The type of biometrics used is outside the scope of SKS and is usually established during enrollment.

The biometric protection option is only intended to be applied to [User API](#) methods like [signHashedData](#).

## 6 Session Security Mechanisms

After the [SessionKey](#) has been created the actual provisioning methods can be called. Depending on the specific method downloaded data may be confidential or need to be authenticated. For certain operations the SKS needs to prove for the issuer that sent data indeed stems from internal SKS operations which is referred to as attestations.

This section describes the security mechanisms used during a provisioning session. Also see [SessionKeyLimit](#).

String literals like "**Encryption Key**" featured in the following definitions **must** be supplied "as is" *without* length indicators, while when being a part of MAC or attestation *Data* arguments **must** be treated as described in [Data Types](#).

### 6.1 Encrypted Data

During provisioning encrypted data is occasionally exchanged between the issuer and the SKS. The encryption key is created by the following key derivation scheme:

**EncryptionKey** = [HMAC-SHA256](#) ([SessionKey](#), "**Encryption Key**")

**EncryptionKey** **must** only be used with the [AES256-CBC](#) algorithm. Note that the IV (Initialization Vector) **must** always be *prepended* to the encrypted data as in [XML Encryption](#).

### 6.2 MAC Operations

In order to verify the integrity of provisioned data, many of the provisioning methods mandate that the data-carrying arguments are included in a MAC (Message Authentication Code) operation as well. MAC operations use the following scheme:

**MAC** = [HMAC-SHA256](#) ([SessionKey](#) || *MethodName* || [MACSequenceCounter](#), *Data*)

*MethodName* is the string literal of the target method like "**closeProvisioningSession**", while *Data* represents the arguments as specified for the actual method. Note that individual elements featured in *Data* **must** use the representation described in [Data Types](#).

After each MAC operation, [MACSequenceCounter](#) **must** be incremented by one. Due the use of a sequence counter, the provisioning system **must** honor the order of objects as defined by the issuer.

### 6.3 Attestations

Attestations created by the SKS are identical to MAC Operations where *MethodName* is set to "**Device Attestation**".

### 6.4 Target Key Reference

In order to perform post provisioning operations the issuer must provide evidence of ownership to keys. *Target Key Reference* denotes a key management authorization signature scheme using the [KeyManagementKey](#) associated with the "owning" provisioning object of the target key (see [Provisioning Objects](#)) according to the following:

**Authorization** = *Sign* ([KeyManagementKey](#)<sub>target</sub>,  
[HMAC-SHA256](#) ([SessionKey](#)<sub>current</sub> || [Device ID](#), [End-Entity Certificate](#)<sub>target</sub>))

Notes:

- All elements **must** be represented "as is" in the HMAC operation, *excluding* length information
- *Sign* **must** use an [PKCS #1](#) RSASSA signature for RSA keys and [ECDSA](#) for EC keys with the *private* key associated with [KeyManagementKey](#), and utilizing [SHA256](#) as hash function
- An SKS **must** verify that the signature validates with respect to the *public* key ([KeyManagementKey](#)) as well as checking that [End-Entity Certificate](#) matches **TargetKeyHandle**
- If a [KeyManagementKey](#) is not present in the target key's provisioning object, the key is considered "not updatable" and the provisioning session **must** be aborted
- The provisioning session **must** be aborted if the [PrivacyEnabled](#) flag differs between the original and the updating session.

## 7 Detailed Operation

This chapter describes the SKS API in detail.

### 7.1 Data Types

The table below shows the data types used by the SKS API. Note that multi-byte integers **must** be stored in big-endian fashion whenever they are *serialized* like in MAC operations. Also see [Method List](#).

Type	Length	Description
byte	1	Unsigned byte (0 - 0xFF)
bool	1	Byte containing 0x01 (true) or 0x00 (false)
short	2	Unsigned two-byte integer (0 - 0xFFFF)
int	4	Unsigned four-byte integer (0 - 0xFFFFFFFF)
byte[]	2 + length	Array of bytes with a leading “short” holding the length of the data
blob	4 + length	Long array of bytes with a leading “int” holding the length of the data
id	2 + length	Special form of byte[] which <b>must</b> contain an 1-32 byte string according to the <a href="#">XML Schema</a> data type <i>NCName</i> but restricted to:   a-z   A-Z   0-9   .   _   -
uri	2 + length	<a href="#">UTF-8</a> encoded byte[] array which <b>must not</b> exceed 1000 bytes

If an array is followed by a number in brackets (byte[32]) it means that the array **must** be exactly of that length.

Variables and literals that represent textual data **must** be [UTF-8](#) encoded and *not* include terminating null characters; they are in this specification considered equivalent to byte[].

Note that length indicators are only applicable to *array objects* when included in MAC operations, or when they are serialized.

## 7.2 Return Values

All methods return a single-byte status code. In case the status is  $\neq 0$  there is an error and any expected succeeding values **must not** be read as they are not supposed to be available. Instead there **must** be a second return value containing a [UTF-8](#) encoded description in *English* to be used for logging and debugging purposes as shown below:

Name	Type	Description
Status	byte	Non-zero (error) value
ErrorMessage	byte[]	A human-readable error description

## 7.3 Error Codes

The following table shows the standard SKS error-codes:

Name	Value	Description
ERROR_AUTHORIZATION	0x01	Non-fatal error returned when there is something wrong with a supplied PIN or PUK code. See <a href="#">getKeyProtectionInfo</a>
ERROR_NOT_ALLOWED	0x02	Operation is not allowed
ERROR_STORAGE	0x03	No persistent storage available for the operation
ERROR_MAC	0x04	MAC does not match supplied data
ERROR_CRYPTO	0x05	Various cryptographic errors
ERROR_NO_SESSION	0x06	Provisioning session not found
ERROR_NO_KEY	0x07	Key not found
ERROR_ALGORITHM	0x08	Unknown or non-matching algorithm
ERROR_OPTION	0x09	Invalid or unsupported option
ERROR_INTERNAL	0x0A	Internal error
ERROR_EXTERNAL	0x0B	External error like communication link failure
ERROR_USER_ABORT	0x0C	User aborted PIN input or similar
ERROR_NOT_AVAILABLE	0x0D	External error when a requested SKS is unavailable

## 7.4 Method List

This section provides a list of the SKS methods. The number in square brackets denotes the *decimal value* used to identify the method in a call. Method calls are formatted as strings of bytes where the first byte holds the method ID and the succeeding bytes the applicable argument data. [User API](#) methods have method IDs  $\geq 100$ .

*Note: The described API is adapted for an SKS using low-level byte-streams for communication. However, the SKS design is equally applicable to API schemes using high-level objects and exceptions. The only thing that **must** remain intact are the cryptographic operations including how objects are represented in MACs.*

Note that a **KeyHandle** in this specification always refers to a *key entry*. See [Key Entries](#).

# getDeviceInfo [1]

## Input

Name	Type	Description
<i>This method does not have any input arguments</i>		

## Output

Name	Type	Description
Status	byte	See <a href="#">Return Values</a>
APILevel	short	100 (1.00) => Applies to <i>this</i> API specification
DeviceType	byte	Holds basic device data. See <a href="#">DeviceType</a>
UpdateURL	uri	URL pointing to a firmware update service or a zero length array. See <a href="#">updateFirmware</a>
VendorName	byte[]	1-128 byte string holding the name of the vendor
VendorDescription	byte[]	1-128 byte string holding a vendor description of the SKS device
PathLength	byte	Non-zero value holding the number of <a href="#">X509Certificate</a> objects
X509Certificate...	byte[]	DER encoded <a href="#">X.509</a> certificate object <i>repeated</i> as defined by <a href="#">PathLength</a>
SupportedAlgorithms	short	Non-zero value holding the number of <a href="#">SupportedAlgorithm</a> objects
SupportedAlgorithm...	uri	Algorithm URI <i>repeated</i> as defined by <a href="#">SupportedAlgorithms</a> . See <a href="#">Algorithm Support</a>
RSAXponentSupport	bool	True if the issuer may specify an <i>explicit</i> exponent value. See <a href="#">createKeyEntry</a>
RSAKeySizes	byte	Non-zero value holding the number of <a href="#">RSAKeySize</a> objects
RSAKeySize...	short	Holds an RSA key size in <i>bits</i> and is <i>repeated</i> as defined by <a href="#">RSAKeySizes</a> . See <a href="#">Algorithm Support</a>
CryptoDataSize	int	Maximum number of bytes in the <a href="#">Data</a> argument of cryptographic methods
ExtensionDataSize	int	Maximum size of <a href="#">ExtensionData</a> objects
DevicePINSupport	bool	True if the SKS supports a device PIN. See <a href="#">createKeyEntry</a>
BiometricSupport	bool	True if the SKS supports biometric authentication options. See <a href="#">Biometric Protection</a>

[getDeviceData](#) lists the core characteristics of an SKS which is used by provisioning schemes like [KeyGen2](#).

The [X509Certificate](#) objects **must** form an *ordered* and *contiguous* certificate path so that the *first* object contains the actual SKS [Device Certificate](#). The path does though not have to be complete (include all upper-level CAs).

[RSAKeySizes](#) **must** be specified in *ascending order*.

A compliant SKS **must** support [ExtensionData](#) objects with a size of at least 65536 bytes.

A compliant SKS **must** support a [CryptoDataSize](#) of at least 16384 bytes.

For EC key generation see [Elliptic Curves](#).

*Continued on the next page...*

**DeviceType** contains a set of fields according to the following table:

Bit	Value	Label	Description
0-1	0x00	<b>LOCATION_EXTERNAL</b>	Connected device
	0x01	<b>LOCATION_EMBEDDED</b>	Embedded in the client platform
	0x02	<b>LOCATION_SOCKETED</b>	Mounted inside a socket
	0x03	<b>LOCATION_SIM</b>	SIM/USIM card
2-3	0x00	<b>TYPE_SOFTWARE</b>	Software implementation
	0x04	<b>TYPE_HARDWARE</b>	Unqualified hardware implementation
	0x08	<b>TYPE_HSM</b>	Hardware Security Module
	0x0C	<b>TYPE_CPU</b>	Implemented inside of the main CPU
4-7	-	-	-

## createProvisioningSession [2]

### Input

Name	Type	Description
<b>Algorithm</b>	uri	Session creation algorithm URI. See next page
<b>PrivacyEnabled</b>	bool	If true the PEP ( <a href="#">Privacy Enabled Provisioning</a> ) mode <b>must</b> be honored
<b>ServerSessionID</b>	id	Server-created provisioning ID which <b>should</b> be unique for each session
<b>ServerEphemeralKey</b>	byte[]	Server-created ephemeral ECDH key. See <a href="#">ServerEphemeralKey</a>
<b>IssuerURI</b>	uri	URI associated with the issuer. See <a href="#">IssuerURI</a>
<b>KeyManagementKey</b>	byte[]	Key management key or zero length array. See <a href="#">KeyManagementKey</a>
<b>ClientTime</b>	int	Locally acquired time in UNIX “epoch” format in <i>seconds</i> . See <a href="#">ClientTime</a>
<b>SessionLifeTime</b>	int	Validity of the provisioning session in seconds. See <a href="#">SessionLifeTime</a>
<b>SessionKeyLimit</b>	short	Upper limit of <b>SessionKey</b> operations. See <a href="#">SessionKeyLimit</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>ClientSessionID</b>	id	SKS-created provisioning ID which <b>must</b> be unique for each session
<b>ClientEphemeralKey</b>	byte[]	SKS-created ephemeral ECDH key. See <a href="#">ClientEphemeralKey</a>
<b>Attestation</b>	byte[]	Session creation attestation signature
<b>ProvisioningHandle</b>	int	Non-zero local handle to created provisioning session

**createProvisioningSession** establishes a *persistent session key* that is only known by the issuer and the SKS for usage in subsequent provisioning steps. In addition, the SKS is *optionally* authenticated by the issuer.

*Continued on the next page...*

Shown below is the mandatory to support SKS session key creation algorithm:

<http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.s1>

- Generate a for this SKS *unique* `ClientSessionID`
- Output `ClientSessionID`
- Generate an *ephemeral* ECDH key-pair `EKP` using *the same named curve* as `ServerEphemeralKey`
- Output `ClientEphemeralKey = EKP.PublicKey`
- Apply the [SP800-56A](#) ECC CDH primitive on `EKP.PrivateKey` and `ServerEphemeralKey` creating a shared secret `z`
- Define internal variable: `byte[32] SessionKey`
- Set `SessionKey = HMAC-SHA256 (z, ClientSessionID || // KDF (Key Derivation Function)  
ServerSessionID ||  
IssuerURI ||  
Device ID)`
- Output `Attestation = Sign (Attestation Private Key, // See Architecture  
HMAC-SHA256 (SessionKey, Algorithm ||  
PrivacyEnabled ||  
ServerEphemeralKey ||  
EKP.PublicKey ||  
KeyManagementKey ||  
ClientTime ||  
SessionLifeTime ||  
SessionKeyLimit))`
- Define internal variable: `short MACSequenceCounter` and set it to *zero*
- Store `SessionKey, Algorithm, PrivacyEnabled, MACSequenceCounter, ClientSessionID, ServerSessionID, IssuerURI, KeyManagementKey, ClientTime, SessionLifeTime` and `SessionKeyLimit` in the [Credential Database](#) and return a handle to the database entry in `ProvisioningHandle`
- Output `ProvisioningHandle`

Note that individual elements featured in the *argument* (e.g. `ClientSessionID`) to the HMAC operations **must** be represented as described in [Data Types](#).

Creation of a session key is an *atomic* operation.

Continued on the next page...

## Remarks

If any succeeding operation in the same provisioning session, is regarded as incorrect by the SKS, *the session **must** be terminated and removed from internal storage including all associated data created in the session.*

An SKS **should** only constrain the number of simultaneous sessions due to lack of storage.

A provisioning session **should not** be terminated due to power down of an SKS.

**Algorithm** defines the creation of **SessionKey** but also the integrity, confidentiality, and attestation mechanisms used during the provisioning session. See [Session Security Mechanisms](#).

Using **KeyGen2 IssuerURI** is the URL which *invoked* the **createProvisioningSession** method.

**ServerEphemeralKey** and **ClientEphemeralKey** **must** be in [X.509](#) DER format and **must** match the elliptic curve capabilities given by [getDeviceInfo](#).

In the [E2ES](#) mode the *Sign* function **must** use [PKCS #1](#) RSASSA signatures for RSA keys and [ECDSA](#) for EC keys with [SHA256](#) as the hash function. The distinction between RSA and ECDSA keys is performed through the [Device Certificate](#) (see [getDeviceInfo](#)) which in [KeyGen2](#) is supplied as well as a part of the response to the issuer.

In the [Privacy Enabled Provisioning](#) mode the *Sign* function **must** only transfer the result of the [HMAC-SHA256](#) operation.

**ProvisioningHandle** **must** be *static, unique* and never be reused.

When **ClientTime** is transferred through a protocol such as [KeyGen2](#) it **must** always as a *minimum* have seconds resolution otherwise serious interoperability issues will occur. Possible milliseconds **must** though be *truncated* during the HMAC calculation.

It is **recommended** setting **SessionLifetime** as low as possible to enable efficient automatic “cleanup” of possible aborted provisioning sessions.

The **SessionKeyLimit** attribute **must** be large enough to handle all **SessionKey** related operations required during the rest of the provisioning session, otherwise the session **must** be terminated. See [Session Security Mechanisms](#). Note that methods like [importSymmetricKey](#) and [pp\\_deleteKey](#) actually use *two* **SessionKey** operations.

A **KeyManagementKey** **must** be supplied if provisioned objects should be *updatable in a future session* (see [pp\\_deleteKey](#), [pp\\_unlockKey](#), [pp\\_updateKey](#), and [pp\\_cloneKeyProtection](#)), else this item **must** be a zero-length array.

A **KeyManagementKey** **must** either be an RSA or an [ECDSA](#) public key in [X.509](#) DER format, compatible with the SKS [Algorithm Support](#).

*Continued on the next page...*

On the server side the following **should** be performed:

Server Response Validation		
<ul style="list-style-type: none"><li>Decide if <b>DeviceCertificatePath</b> of <b>ProvisioningInitializationResponse</b> is to be accepted/trusted.</li><li>Run the the same <b>SP800-56A</b> procedure and KDF as for the SKS but now using <b>ClientEphemeralKey</b> and the saved private key of <b>ServerEphemeralKey</b> to obtain <b>SessionKey</b></li><li><b>VerifySignature</b> (<b>Device Certificate</b> .<b>PublicKey</b>,                   <b>Attestation</b>,                   <b>HMAC-SHA256</b> (<b>SessionKey</b>, <b>Algorithm</b>                                      <b>PrivacyEnabled</b>                                      <b>ServerEphemeralKey</b>                                      <b>ClientEphemeralKey</b>                                      <b>KeyManagementKey</b>                                      <b>ClientTime</b>                                      <b>SessionLifeTime</b>                                      <b>SessionKeyLimit</b>))</li></ul>		
		// Received
		// Received
		// Saved
		// Saved
		// Saved
		// Received
		// Saved
		// Received
		// Saved
		// Saved

If all tests above succeed the issuer server may continue with the actual provisioning process.

Note that in the **Privacy Enabled Provisioning** mode the **DeviceCertificatePath** does not apply, and **VerifySignature** is replaced by a straight comparison between **Attestation** and the output from the **HMAC-SHA256** operation.

*Continued on the next page...*

When using [KeyGen2](#) the *input* to `createProvisioningSession` is expressed as shown in the fragment below:

```
<ProvisioningInitializationRequest ID="_0fa47ab3c00c ... a67992b6ac61c"
    SubmitURL="https://ca.example.com/enroll"
    SessionLifeTime="50000"
    SessionKeyLimit="25"
    Algorithm="http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.s1" ... >

  <ServerEphemeralKey>
    <ds11:ECKeyValue>
      <ds11:NamedCurve URI="urn:oid:1.2.840.10045.3.1.7"/>
      <ds11:PublicKey>JK/mSALhBpUjjPAe/ ... fXG8z17eZV3mVDZTBM</ds11:PublicKey>
    </ds11:ECKeyValue>
  </ServerEphemeralKey>
  <KeyManagementKey>
    <ds:RSAKeyValue>
      <ds:Modulus>ALhBpUjJK/mSjPAe/ ... fXG8z1V3mVDZTBM7eZ</ds:Modulus>
      <ds:Exponent>AQAB</ds:Exponent>
    </ds:RSAKeyValue>
  </KeyManagementKey>

</ProvisioningInitializationRequest>
```

Notes:

The [KeyManagementKey](#) element is *optional*.

If the [PrivacyEnabled](#) attribute is missing the [E2ES](#) mode is assumed.

The table below illustrates argument mapping:

KeyGen2 Element	SKS Counterpart
ProvisioningInitializationRequest@ID	ServerSessionID
ProvisioningInitializationRequest@SubmitURL	IssuerURI
ProvisioningInitializationRequest@SessionLifeTime	SessionLifeTime
ProvisioningInitializationRequest@SessionKeyLimit	SessionKeyLimit
ProvisioningInitializationRequest@Algorithm	Algorithm
ProvisioningInitializationRequest@PrivacyEnabled	PrivacyEnabled
ServerEphemeralKey/ECKeyValue	ServerEphemeralKey
KeyManagementKey	KeyManagementKey
N/A - Gathered by the local provisioning middleware	ClientTime

Continued on the next page...

When using [KeyGen2](#) the *output* from `createProvisioningSession` is translated as shown in the fragment below:

```
<ProvisioningInitializationResponse ID="_126992b6 ... a8a6b484db8f"
    ServerSessionID="_0fa47ab3c00c ... a67992b6ac61c"
    ClientTime="2010-03-18T11:23:29Z"
    ServerCertificateFingerprint="AvDWx6xbg3GDGzdz ... yJk8Js0Oul+Ba/Xc8="
    Attestation="Ob7MvaXC/rNx/rkNZJEo ... 8lch/6snglszfpElrggQfl" ... >

<ClientEphemeralKey>
  <ds11:ECKeyValue>
    <ds11:NamedCurve URI="urn:oid:1.2.840.10045.3.1.7"/>
    <ds11:PublicKey>PRZre90SQLp ... 16m9FokKxV3F40Y=</ds11:PublicKey>
  </ds11:ECKeyValue>
</ClientEphemeralKey>
<DeviceCertificatePath>
  <ds:X509Data>
    <ds:X509Certificate>MIIC2TCCAcGgAwIBAg ... hugc53W4nNzggt2w==</ds:X509Certificate>
  </ds:X509Data>
</DeviceCertificatePath>
<ds:Signature>
  <ds:SignedInfo>
    <ds:CanonicalizationMethod Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
    <ds:SignatureMethod Algorithm="http://www.w3.org/2001/04/xmldsig-more#hmac-sha256" />
    <ds:Reference URI="#_126992b6 ... a8a6b484db8f">
      <ds:Transforms>
        <ds:Transform Algorithm="http://www.w3.org/2000/09/xmldsig#enveloped-signature" />
        <ds:Transform Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
      </ds:Transforms>
      <ds:DigestMethod Algorithm="http://www.w3.org/2001/04/xmldsig-more#sha256" />
      <ds:DigestValue>yLD0zNA48Xt9xXNHuBUIK0hL51zn0SYj2IfDXm42PLc=</ds:DigestValue>
    </ds:Reference>
  </ds:SignedInfo>
  <ds:SignatureValue>aRiSdmrn/KgtjqTReF+6DOulemRuw2xV9yuOPAlMj8=</ds:SignatureValue>
  <ds:KeyInfo>
    <ds:KeyName>derived-session-key</ds:KeyName>
  </ds:KeyInfo>
</ds:Signature>

</ProvisioningInitializationResponse>
```

The table below illustrates mapping:

KeyGen2 Element	SKS Counterpart
<code>ProvisioningInitializationResponse@ID</code>	<code>ClientSessionID</code>
<code>ProvisioningInitializationResponse@ServerSessionID</code>	<code>Input.ServerSessionID</code>
<code>ProvisioningInitializationResponse@ClientTime</code>	<code>Input.ClientTime</code>
<code>ProvisioningInitializationResponse@Attestation</code>	<code>Attestation</code>
<code>ClientEphemeralKey/ECKeyValue</code>	<code>ClientEphemeralKey</code>
<code>DeviceCertificatePath/X509Data/X509Certificate</code>	<i>Optional:</i> Certificate <i>path</i> from <a href="#">getDeviceInfo</a>
<code>Signature/SignatureValue</code>	Created with <a href="#">signProvisioningSessionData</a>

In the standard [E2ES](#) mode the `DeviceCertificatePath` **must** be available for verification of the `Attestation` signature as well as for identification of the SKS container. The `Signature` element holds a standard enveloped [XML Signature](#). Also see [Security Considerations](#).

## closeProvisioningSession [3]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>Nonce</b>	byte[]	Server generated 1-32 byte nonce value
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Attestation</b>	byte[32]	Session termination attestation signature. See <a href="#">Attestations</a>

**closeProvisioningSession** terminates a provisioning session and returns a proof of successful operation to the issuer. However, success status **must** only be returned if *all* of the following conditions are valid:

- There is an open provisioning session associated with **ProvisioningHandle**
- The **MAC** computes correctly using the method described in [MAC Operations](#) where *Data* is arranged as follows:  
$$Data = \text{ClientSessionID} \parallel \text{ServerSessionID} \parallel \text{IssuerURI} \parallel \text{Nonce}$$
- All generated keys are fully provisioned which means that matching public key certificates have been deployed and checked regarding disallowed duplicates. See [setCertificatePath](#)
- [EndorsedAlgorithm](#) URIs match the provisioned key material with respect to symmetric or asymmetric operations as well as to length. Asymmetric keys are also tested for RSA and EC algorithm compliance
- There are no unreferenced PIN or PUK policy objects. See [createPUKPolicy](#) and [createPINPolicy](#)
- The post provisioning operations succeed during the final *commit*. See [Transaction Based Operation](#)

If verification is successful, **closeProvisioningSession** **must** also *reassign provisioning session ownership* to the current (closing) session for *all* objects belonging to sessions that have been subject to a post provisioning operation. The original session objects **must** subsequently be deleted since they have no mission anymore. Also see [Provisioning Objects](#).

If verification fails, *all* objects created in the session **must** be deleted and post provisioning operations **must** be rolled back.

When a provisioning session has been successfully closed by this method, it remains stored until all associated keys have been deleted.

Using [KeyGen2](#) **closeProvisioningSession** is invoked as the last step of processing [ProvisioningFinalizationRequest](#) where the top element holds the associated **MAC** and **Nonce** attributes.

The **Attestation** object is created by attesting the following *Data*:

$$Data = \text{Nonce} \parallel \text{ProvisioningHandle}.\text{Algorithm}$$

Also see [SessionKeyLimit](#).

A *successful* [KeyGen2](#) response would typically look like:

```
<ProvisioningFinalizationResponse ID="_126992b6 ... a8a6b484db8f"
  ServerSessionID="_0fa47ab3c00c ... a67992b6ac61c"
  Attestation="gEWzCCD ... 0w81L/Is2W0UYNE=" ... />
```

## enumerateProvisioningSessions [4]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Input enumeration handle
<b>ProvisioningState</b>	bool	If true list only <i>open</i> provisioning sessions. If false list only <i>closed</i> dittos

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>ProvisioningHandle</b>	int	Output enumeration handle
<i>The following elements <b>must</b> be set to zero if the output <b>ProvisioningHandle</b> = 0</i>		
<b>Algorithm</b>	uri	See <a href="#">createProvisioningSession</a>
<b>PrivacyEnabled</b>	bool	
<b>KeyManagementKey</b>	byte[]	
<b>ClientTime</b>	int	
<b>SessionLifeTime</b>	int	
<b>ServerSessionID</b>	id	
<b>ClientSessionID</b>	id	
<b>IssuerURI</b>	uri	

**enumerateProvisioningSessions** is primarily intended to be used by provisioning middleware for retrieving handles to *open* provisioning sessions in sessions that are interrupted due to a certification process or similar.

In addition, users of portable SKSes (like smart cards), may carry out provisioning steps on *different* computers through this method.

**enumerateProvisioningSessions** may also be useful for debugging and “cleaning” purposes.

The input **ProvisioningHandle** **must** initially be set to 0 to start an enumeration round.

Succeeding calls **must** use the output **ProvisioningHandle** as input to the next call.

When **enumerateProvisioningSessions** returns with a **ProvisioningHandle** = 0 there are no more provisioning objects to read.

## abortProvisioningSession [5]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**abortProvisioningSession** is intended to be used by provisioning middleware if an unrecoverable error occurs in the communication with the issuer, or if a user cancels a session. If there is a matching and still *open* provisioning session, all associated data **must** be removed from the SKS, otherwise an error **must** be returned.

## signProvisioningSessionData [6]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>Data</b>	byte[]	Data to be signed

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Signature</b>	byte[32]	Signed data

**signProvisioningSessionData** signs *arbitrary data* that is supplied *by the provisioning middleware*.

The purpose of **signProvisioningSessionData** is adding data integrity to provisioning messages from clients to issuers.

The signature scheme is as follows:

**Signature** = [HMAC-SHA256](#) ([SessionKey](#) || "External Signature", **Data**)

Note that **Data** **must** be used “as is” in the HMAC operation, *excluding* length information.

A *relying party* **must** distinguish between such signatures and [Attestations](#) since only the latter are actually vouched for by the SKS.

Also see [SessionKeyLimit](#).

## createPUKPolicy [7]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>ID</b>	id	<i>External name</i> of the PUK policy object. See <a href="#">Object IDs</a>
<b>PUKValue</b>	byte[]	Encrypted PUK value. See <a href="#">Encrypted Data</a>
<b>Format</b>	byte	Format of PUK strings. See <a href="#">PIN and PUK Formats</a>
<b>RetryLimit</b>	short	Number of incorrect PUK values ( <i>in a sequence</i> ), forcing the PUK object to permanently lock up. A zero value indicates that there is no limit but that the SKS will introduce an <i>internal</i> 1-10 second delay <i>before</i> acting on an unlock operation in order to thwart exhaustive attacks
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>PUKPolicyHandle</b>	int	Non-zero handle to created PUK policy object

**createPUKPolicy** creates a PUK policy object in the [Credential Database](#) to be referenced by subsequent calls to the [createPINPolicy](#) method.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = ID || PUKValue || Format || RetryLimit

Note that **PUKValue** is MACed in encrypted form and *then* decrypted by the SKS before storing.

The purpose of a PUK is to facilitate a master key for unlocking keys that have locked-up due to faulty PIN entries. See [unlockKey](#).

PUK policy objects are not directly addressable after provisioning; in order to read PUK policy data, you need to use an associated key handle as input. See [getKeyProtectionInfo](#).

# createPINPolicy [8]

## Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>ID</b>	id	<i>External name</i> of the PIN policy object. See <a href="#">Object IDs</a>
<b>PUKPolicyHandle</b>	int	Handle to a governing PUK policy object or zero
<b>UserDefined</b>	bool	True if PINs belonging to keys governed by the PIN policy are supposed to be set by the user or by the issuer. See <a href="#">PINValue</a>
<b>UserModifiable</b>	bool	True if PINs can be changed by the user after provisioning
<b>Format</b>	byte	Format of PIN strings. See <a href="#">PIN and PUK Formats</a>
<b>RetryLimit</b>	short	Non-zero value holding the number of incorrect PIN values ( <i>in a sequence</i> ), forcing a key to lock up
<b>Grouping</b>	byte	See <a href="#">PIN Grouping</a>
<b>PatternRestrictions</b>	byte	See <a href="#">PIN Patterns</a>
<b>MinLength</b>	short	Minimum <i>decoded</i> PIN length in bytes. See <a href="#">PIN and PUK Formats</a>
<b>MaxLength</b>	short	Maximum <i>decoded</i> PIN length in bytes. See <a href="#">PIN and PUK Formats</a>
<b>InputMethod</b>	byte	See <a href="#">PIN Input Methods</a>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>PINPolicyHandle</b>	int	Non-zero handle to created PIN policy object

**createPINPolicy** creates a PIN policy object in the [Credential Database](#) to be referenced by subsequent calls to the [createKeyEntry](#) method.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = ID || *PUKReference* || **UserDefined** || **UserModifiable** || **Format** || **RetryLimit** ||  
**Grouping** || **PatternRestrictions** || **MinLength** || **MaxLength** || **InputMethod**

*PUKReference* is set to "#N/A" if **PUKPolicyHandle** is zero, else it is set to the **ID** of the referenced PUK policy object.

If **PUKPolicyHandle** is zero no PUK is associated with the PIN policy object.

PIN policy objects are not directly addressable after provisioning; in order to read PIN policy data, you need to use an associated key handle as input. See [getKeyProtectionInfo](#).

# createKeyEntry [9]

## Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>ID</b>	id	<i>External name</i> of the key. See <a href="#">Object IDs</a>
<b>Algorithm</b>	uri	Key generation and attestation algorithm URI. See next page
<b>ServerSeed</b>	byte[]	Server input to the random number generation process. See <a href="#">ServerSeed</a>
<b>DevicePINProtection</b>	bool	True if the key is to be protected by a <i>device PIN</i> . See <a href="#">Key Protection Objects</a>
<b>PINPolicyHandle</b>	int	Handle to a governing PIN policy object or zero. See <a href="#">createPINPolicy</a>
<b>PINValue</b>	byte[]	See <a href="#">PINValue</a> , <a href="#">PIN Patterns</a> and <a href="#">PIN Grouping</a>
<b>EnablePINCaching</b>	bool	True if middleware <b>may</b> cache PINs for this key. See <a href="#">EnablePINCaching</a>
<b>BiometricProtection</b>	byte	See <a href="#">Biometric Protection</a>
<b>ExportProtection</b>	byte	See <a href="#">Key Export</a>
<b>DeleteProtection</b>	byte	See <a href="#">Key Delete</a>
<b>AppUsage</b>	byte	See <a href="#">Key Application Usage</a>
<b>FriendlyName</b>	byte[]	String of 0-128 bytes that will be associated with this key for use in GUIs
<b>KeySpecifier</b>	byte[]	Algorithm and length of key to be created. See <a href="#">KeySpecifier</a>
<b>EndorsedAlgorithms</b>	byte	Value [0..255] holding the number of <b>EndorsedAlgorithm</b> URIs
<b>EndorsedAlgorithm...</b>	uri	Endorsed algorithm URI <i>repeated</i> as defined by <b>EndorsedAlgorithms</b>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>KeyHandle</b>	int	Non-zero local handle to created key entry
<b>PublicKey</b>	byte[]	Generated public key in <a href="#">X.509</a> DER representation
<b>Attestation</b>	byte[32]	See <a href="#">Attestation</a>

**createKeyEntry** generates an asymmetric key-pair according to the issuer's specification. In addition, **createKeyEntry** creates a *key entry* (see [Key Entries](#)) in the [Credential Database](#) where the key-pair and its protection attributes are stored.

*Continued on the next page...*

The following operations match the mandatory to support key generation and attestation algorithm:

http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.k1

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

$$\text{Data} = \text{ID} \parallel \text{Algorithm} \parallel \text{ServerSeed} \parallel \text{PINPolicyReference} \parallel \text{PINValueReference} \parallel$$
$$\text{EnablePINCaching} \parallel \text{BiometricProtection} \parallel \text{ExportProtection} \parallel$$
$$\text{DeleteProtection} \parallel \text{AppUsage} \parallel \text{FriendlyName} \parallel$$
$$\text{KeySpecifier} [ \parallel \text{EndorsedAlgorithm} \dots ]$$

*PINPolicyReference* is set to "#Device PIN" if *DevicePINProtection* is true, to "#N/A" if *PINPolicyHandle* is zero, else it is set to the ID of the referenced PIN policy object.

*PINValueReference* is set to "#N/A" if *PINPolicyHandle* is zero, or if *DevicePINProtection* is true, or if the PIN is [UserDefined](#), else it is set to the *encrypted PINValue*.

**KeySpecifier** denotes a blob encoded as follows depending on the requested key algorithm:

RSA	
byte	Type of key to be generated: 0x00 = RSA
short	RSA key size in bits. See <a href="#">getDeviceInfo</a>
int	Zero (use default) or a defined exponent. See <a href="#">getDeviceInfo</a>

ECDSA/ECDH	
byte	Type of key to be generated: 0x01 = EC
uri	Curve name URI where the URI is stored <i>without</i> length indicator. See <a href="#">Elliptic Curves</a>

**Attestation** vouches for that generated key-pairs actually reside in the SKS by attesting (see [Attestations](#)) keys according to the following *Data* scheme:

$$\text{Data} = \text{ID} \parallel \text{PublicKey}$$

#### Remarks

**KeyHandle** **must** be *static, unique and never be reused*. Note that a **KeyHandle** returned by **createKeyEntry** **must not** be featured in [User API](#) operations until the associated provisioning session has been closed (see [closeProvisioningSession](#)).

Object IDs for [createKeyEntry](#), [createPINPolicy](#) and [createPUKPolicy](#) *share a common namespace* but the namespace is entirely local to the *provisioning session*. Although only static identifiers are used in the examples, Object IDs *may be randomized* to increase entropy of [MAC Operations](#).

A compliant SKS **should** use 65537 as the default RSA exponent value.

**ServerSeed** **must** be a 0-32 byte binary string holding a *random number seed*. How **ServerSeed** is applied to the random number generation process is *unspecified*. The only requirement is that it **must not** be able *reducing* the entropy.

A non-zero **BiometricProtection** value presumes that the target SKS supports [Biometric Protection](#), otherwise an **error must be** returned. See [getDeviceInfo](#).

*Continued on the next page...*

**EndorsedAlgorithm** URIs **must** be *sorted in ascending alphabetical order* before calling **createKeyEntry**.

**EndorsedAlgorithm** URIs **must** be checked for compatibility with [Algorithm Support](#).

**EndorsedAlgorithm** compliance **must** be *enforced* by the [User API](#).

**EndorsedAlgorithm** URIs **must not** be checked against actual key material during **createKeyEntry**. This check **must** be *deferred* to [closeProvisioningSession](#).

If no **EndorsedAlgorithm** URIs are specified, *the key is only constrained by the key material*.

With the special algorithm `http://xmlns.webpki.org/keygen2/1.0#algorithm.none` (which is only permitted as a single **EndorsedAlgorithm** item), keys **must** be *disabled* from executing cryptographic operations through the [User API](#).

A set **DevicePINProtection** presumes that the target SKS supports a “device PUK/PIN”, otherwise an *error must be* returned. The characteristics of device PINs are out of scope for the SKS specification. See [getDeviceInfo](#).

**DevicePINProtection** **must not** be combined with local PIN policy objects.

**EnablePINCaching** **must** only be used with keys protected by local PIN policy objects having the [InputMethod](#) set to “trusted-gui”.

**PINValue** objects **must** be set by the *caller* as illustrated by the following pseudo code:

```
if (PINPolicyHandle == 0) // No PIN or device PIN
{
    PINValue = zero length array;
}
else if (PINPolicyHandle.UsedDefined) // see UserDefined
{
    PINValue = user-defined clear text PIN value; // taken from a local provisioning GUI
}
else
{
    PINValue = encrypted issuer-set PIN value; // see Encrypted Data
}
```

*Continued on the next page...*

The following XML extract shows a typical key generation (initialization) request in [KeyGen2](#):

```
<KeyCreationRequest Algorithm="http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.k1" ... >
  <PUKPolicy ID="PUK.1" Format="numeric" RetryLimit="3" Value="mjRuO ... 1Oqw" MAC="uPqE ... HIF=">
    <PINPolicy ID="PIN.1" Format="numeric" Grouping="shared" MaxLength="8" MinLength="4"
      PatternRestrictions="three-in-a-row sequence" RetryLimit="3" MAC="gz56 ... 2B7=">
      <KeyEntry ID="Key.1" AppUsage="authentication" MAC="nFRuPgZ ... H2B429S=">
        <EC NamedCurve="urn:oid:1.2.840.10045.3.1.7"/>
      </KeyEntry>
      <KeyEntry ID="Key.2" AppUsage="encryption" MAC="gSg4chh ... H2BEE7=">
        <RSA KeySize="2048"/>
      </KeyEntry>
    </PINPolicy>
  </PUKPolicy>
</KeyCreationRequest>
```

This sequence should be interpreted as a request for an EC key and an RSA key where both keys are protected by a single (shared) user-defined (within the specified policy limits) PIN. The PIN is in turn governed by an issuer-defined, *protocol wise secret* PUK. Also see [KeyGen2 Proxy](#).

In the sample [KeyGen2 default values](#) have been utilized which is why there are few *visible* key generation attributes.

When using [KeyGen2](#) the *output* from `createKeyEntry` is translated as shown in the fragment below:

```
<KeyCreationResponse ... >
  <PublicKey ID="Key.1" Attestation="X2oMtrm8rRL ... XyTvPuTbergHfnJw==">
    <ds11:ECKeYValue>
      <ds11:NamedCurve URI="urn:oid:1.2.840.10045.3.1.7"/>
      <ds11:PublicKey>BMUY+QiZdFJyzozMgQqA ... ptPGNy/LcDVSXx7s/Y=</ds11:PublicKey>
    </ds11:ECKeYValue>
  </PublicKey>
  <PublicKey ID="Key.2" Attestation="TbergHftrm8rRL ... wyTvPX2XoMunJ==">
    <ds:RSAKeYValue>
      <ds:Modulus>ALhBpUjJK/mSjPAe/ ... fXG8z1V3mVDZTBM7eZ</ds:Modulus>
      <ds:Exponent>AQAB</ds:Exponent>
    </ds:RSAKeYValue>
  </PublicKey>
</KeyCreationResponse>
```

A conforming server **must** after receipt of the response verify that the number and IDs of returned keys match the request. In addition, each returned key **must** be checked for correctness regarding attestation data and that the generated public key actually complies with that of the request.

## getKeyHandle [10]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>ID</b>	id	See <a href="#">createKeyEntry</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>KeyHandle</b>	int	Local handle to a key belonging to an <i>open</i> provisioning session

**getKeyHandle** returns a **KeyHandle** based on the provisioning session specific key ID.

An invalid key **must** return an error and abort the provisioning session.

## setCertificatePath [11]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a key-pair belonging to an <i>open</i> provisioning session
<b>PathLength</b>	byte	Non-zero value holding the number of <b>X509Certificate</b> objects in the call
<b>X509Certificate...</b>	byte[]	DER encoded <a href="#">X.509</a> certificate object <i>repeated</i> as defined by <b>PathLength</b>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**setCertificatePath** attaches an [X.509](#) certificate path to an already created key-pair. See [createKeyEntry](#).

The **X509Certificate** objects **must** form an *ordered* and *contiguous* certificate path so that the *first* object contains the [End-Entity Certificate](#) *usually* holding the public key of the target key-pair. The path does though not have to be complete (include all upper-level CAs). Path validity **should** be verified by the provisioning middleware before calling this method.

Individual **X509Certificate** objects **must not** exceed [CryptoDataSize](#).

Note that an SKS **must not** attempt to verify that the [End-Entity Certificate](#) and **KeyHandle.PublicKey** match because that would disable the [restorePrivateKey](#) method. It is the **MAC** operation that is facilitating a cryptographically verifiable binding between the certificate path and the designated key entry.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = **KeyHandle.PublicKey** || **KeyHandle.ID** || **X509Certificate...**

A compliant SKS **must not** accept multiple key entries being associated by the same [End-Entity Certificate](#) unless the conflicting key is subject to a [pp\\_updateKey](#) or [pp\\_deleteKey](#) operation.

The provisioning middleware **should** verify that the public key of the [End-Entity Certificate](#) matches the algorithmic capabilities of the SKS. See [Algorithm Support](#).

*Continued on the next page...*

The following [KeyGen2](#) fragment shows its interaction with `setCertificatePath`:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrm421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
  </CertificatePath>

</ProvisioningFinalizationRequest>
```

The table below illustrates argument mapping:

KeyGen2 Element	SKS Counterpart
CertificatePath@ID	KeyHandle.ID
CertificatePath@MAC	MAC
CertificatePath/X509Data/X509Certificate...	X509Certificate...

The owning `ProvisioningHandle` and local `KeyHandle` can be retrieved by calling [enumerateProvisioningSessions](#) and [getKeyHandle](#) respectively. The request attributes `ProvisioningFinalizationRequest@ClientSessionID` and `ProvisioningFinalizationRequest@ID` hold the [ClientSessionID](#) and [ServerSessionID](#) of the provisioning session.

## importSymmetricKey [12]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a key belonging to an <i>open</i> provisioning session
<b>SymmetricKey</b>	byte[]	“Piggybacked” symmetric key encrypted as described in <a href="#">Encrypted Data</a>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**importSymmetricKey** imports and links a symmetric key to an already created key-pair and certificate.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = [End-Entity Certificate](#) || **SymmetricKey**

Note that **SymmetricKey** objects **must be** MACed in *encrypted form* and *then* decrypted by the SKS before storing.

Symmetric keys **must not** exceed 128 bytes.

With the special [EndorsedAlgorithm](#) `http://xmlns.webpki.org/keygen2/1.0#algorithm.none` arbitrary static shared secrets can be specified. When used together with [exportKey](#), a suitable PIN policy and a [PropertyBag](#) object holding site information, an SKS could then also serve as a *browser password store*.

After **importSymmetricKey** has been called the key entry is marked as “symmetric”. That is, *the private key is disabled* as well as all operations associated with it. See [getKeyAttributes](#).

The [KeyBackup](#).**SERVER** flag of the key **must** be set after execution of **importSymmetricKey**.

*Continued on the next page...*

The following [KeyGen2](#) fragments show the “piggyback” arrangement. First the server issues a key-pair request:

```
<KeyCreationRequest Algorithm="http://xmlns.webpki.org/keygen2/1.0#algorithm.sks.k1" ... >
  <PUKPolicy ID="PUK.1" Format="numeric" RetryLimit="3" Value="mjRuO ... 1Oqw" MAC="uPqE ... HIF=">
    <PINPolicy ID="PIN.1" Format="numeric" MaxLength="8" MinLength="4"
      PatternRestrictions="three-in-a-row sequence" RetryLimit="3" MAC="gz56 ... 2B7=">
      <KeyEntry ID="Key.1" AppUsage="authentication"
        EndorsedAlgorithms="http://www.w3.org/2000/09/xmlsig#hmac-sha1"
        MAC="gSg4chh ... H2BEE7=">
        <RSA KeySize="1024"/>
      </KeyEntry>
    </PINPolicy>
  </PUKPolicy>
</KeyCreationRequest>
```

The request above is identical to requests for PKI except for the *optional* [EndorsedAlgorithm](#) declaration which in the sample limited symmetric key operations to [HMAC-SHA1](#).

After the request the client generates a compatible key-pair response which is *identical* to that of PKI:

```
<KeyCreationResponse ... >
  <PublicKey ID="Key.1" Attestation="TbergHftrm8rRL ... wyTvPX2XoMunJ==">
    <ds:RSAKeyValue>
      <ds:Modulus>ALhBpUjJK/mSjPAe/ ... fXG8z1V3mVDZTBM7eZ</ds:Modulus>
      <ds:Exponent>AQAB</ds:Exponent>
    </ds:RSAKeyValue>
  </PublicKey>
</KeyCreationResponse>
```

The server then responds with the usual certificated public key plus an encrypted “piggybacked” symmetric key:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
  ID="_0fa47ab3c00c ... a67992b6ac61c"
  MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >
  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrm421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <SymmetricKey MAC="je7KiznTil ... vlnumZCjxSI1=">vInt09Esmg94v ... YU3tgldhcNNby</SymmetricKey>
  </CertificatePath>
</ProvisioningFinalizationRequest>
```

For details on how to map keys and sessions, see [setCertificatePath](#).

Note that the [X.509](#) certificate serves as a universal key ID. That is, *SKS treats asymmetric and symmetric keys close to identically*.

## addExtension [13]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a key belonging to an <i>open</i> provisioning session
<b>Type</b>	uri	Type URI. Holds a unique name identifying the extension type
<b>SubType</b>	byte	See table below
<b>Qualifier</b>	byte[]	See table below
<b>ExtensionData</b>	blob	Extension object. Regarding size constraints see <a href="#">getDeviceInfo</a>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**addExtension** adds attribute (extension) data to an already created key-pair and certificate.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = [End-Entity Certificate](#) || **Type** || **SubType** || **Qualifier** || **ExtensionData**

The following table shows **SubType**, **Qualifier** and **ExtensionData** mapping using [KeyGen2](#):

KeyGen2 Element	SubType	Qualifier	ExtensionData
<b>Extension</b>	0x00	N/A	Binary data extracted from <a href="#">Base64</a> encoded XML
<b>EncryptedExtension</b>	0x01	N/A	Encrypted binary data extracted from <a href="#">Base64</a> encoded XML
<b>PropertyBag</b>	0x02	N/A	See <a href="#">PropertyBag</a> canonicalization
<b>Logotype</b>	0x03	<b>MIMETYPE</b>	Binary image data extracted from <a href="#">Base64</a> encoded XML

### Remarks

N/A = zero-length array.

Note the handling of the **EncryptedExtension**: **ExtensionData** which is encrypted as described in [Encrypted Data](#) **must** be MACed in *encrypted form* and *then* decrypted by the SKS before storing.

A compliant SKS **must not** allow a given key to be associated with multiple extensions of the same **Type**. *If multiple objects of the same type are needed, you must define a container type holding these.*

**Type** URIs *do not have to be recognized by the SKS*, since they are intended for interpretation by external applications.

Although not a part of the current SKS specification, an extension *could* be created for consumption by the SKS only, like downloaded [JavaCard](#) code. In that case the associated extension **Type** URI **must** be featured in the SKS *supported algorithm list*. See [getDeviceInfo](#) and [getExtension](#).

**Qualifier** objects **must not** exceed 128 bytes.

*Continued on the next page...*

The *simplified* XML schema extract below describes the [KeyGen2](#) representation of **PropertyBag** objects:

PropertyBag XML Schema
<pre>&lt;xs:element name="PropertyBag"&gt;   &lt;xs:complexType&gt;     &lt;xs:sequence&gt;       &lt;xs:element name="Property" maxOccurs="unbounded"&gt;         &lt;xs:complexType&gt;            &lt;!-- The unique name of the property --&gt;           &lt;xs:attribute name="Name" use="required"/&gt;           &lt;xs:simpleType&gt;             &lt;xs:restriction base="xs:string"&gt;               &lt;xs:minLength value="1"/&gt;               &lt;xs:maxLength value="100"/&gt;             &lt;/xs:restriction&gt;           &lt;/xs:simpleType&gt;         &lt;/xs:attribute&gt;          &lt;!-- The value of the property --&gt;         &lt;xs:attribute name="Value" type="xs:string" use="required"/&gt;          &lt;!-- By default values are read-only but they may be declared as read/writable as well --&gt;         &lt;xs:attribute name="Writable" type="xs:boolean" use="optional"/&gt;        &lt;/xs:complexType&gt;     &lt;/xs:element&gt;   &lt;/xs:sequence&gt;    &lt;!-- Extension type --&gt;   &lt;xs:attribute name="Type" type="xs:anyURI" use="required"/&gt;    &lt;!-- MAC (Message Authentication Code) --&gt;   &lt;xs:attribute name="MAC" type="xs:base64Binary" use="required"/&gt;  &lt;/xs:complexType&gt; &lt;/xs:element&gt;</pre>

A **PropertyBag** **must** be converted to a *binary blob* before storage in SKS and MACing according to the following:

- Each **Property** is translated into a composite object consisting of the following attributes and transformed representation:

Name	Writable	Value
byte[]	bool	byte[]

See [Data Types](#)

- The resulting **Property** objects are *concatenated* in the order they occur in the **PropertyBag**

Note that there are no delimiters added between attributes or objects. The assembled blob holds the actual [ExtensionData](#).

Enforcement of **Property** name uniqueness **may** be delegated to the middleware layer. Also see [setProperty](#).

*Continued on the next page...*

Below is a [KeyGen2](#) fragment showing an **Extension** object holding a [Base64](#) encoded **Information Card**:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrm421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <Extension Type="http://schemas.xmlsoap.org/ws/2005/05/identity"
              MAC="UMRIjeXFd ... CrcqcGkl1=">liBibmHVy85cZS ... B4bWxuczd3dy53My5vc</Extension>
  </CertificatePath>

</ProvisioningFinalizationRequest>
```

For details on how to map keys and sessions, see [setCertificatePath](#).

In the Information Card sample the primary authentication key (for authenticating to the IDP), would preferable be the PKI key associated by **CertificatePath**. That is, the issuance of a managed Information Card and its primary key *can be fully synchronized* making both usage and middleware design straightforward.

The following is a [KeyGen2](#) sample showing the **PropertyBag** and **Logotype** objects added to a symmetric key for usage by a [HOTP](#) application:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrm421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <SymmetricKey MAC="je7KiznTil ... vlnu7rcqcGkl=">vInt09Esmg94v ... YU3tgldhcNNby</SymmetricKey>
    <PropertyBag Type="http://xmlns.webpki.org/keygen2/1.0#provider.ietf-hotp"
              MAC="jIOHDgwl4dO7Kzs ... uEH8MtykIS46JfiJ3N=">
      <Property Name="Counter" Value="0" Writable="true"/>
      <Property Name="Digits" Value="8"/>
    </PropertyBag>
    <Logotype MIMETYPE="image/png"
              Type="http://xmlns.webpki.org/keygen2/1.0#logotype.application"
              MAC="+crSq5fvfx+f ... ZmRnhxlj0d=">iAAABKCAIAAACD ... tm/AAALjUIEQVRA=</Logotype>
  </CertificatePath>

</ProvisioningFinalizationRequest>
```

A [HOTP](#) application would preferably also make the corresponding [KeyCreationRequest](#) operation include an endorsement algorithm definition.

## restorePrivateKey [14]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a key belonging to an <i>open</i> provisioning session
<b>PrivateKey</b>	byte[]	Private key in <a href="#">PKCS #8</a> format wrapped as described in <a href="#">Encrypted Data</a>
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**restorePrivateKey** replaces a generated private key with a key supplied by the issuer.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = [End-Entity Certificate](#) || **PrivateKey**

Note that **PrivateKey** objects **must** be MACed in *encrypted form* and *then* decrypted by the SKS before storing.

The purpose of **restorePrivateKey** (preceded by [setCertificatePath](#)), is to install a certificate and private key that the issuer have generated or have a backup of.

The [KeyBackup](#) .**SERVER** flag of the key **must** be set after execution of **restorePrivateKey**.

The following [KeyGen2](#) fragment shows how credentials that are to be restored should be formatted:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrM421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <PrivateKey MAC="umZCjxSl1zX ... CrcqcGklv4Ki=">cVyZSLiBlbmH ... uczipkcB4bWx3dy53</PrivateKey>
  </CertificatePath>

</ProvisioningFinalizationRequest>
```

For details on how to map keys and sessions, see [setCertificatePath](#).

If **restorePrivateKey** is executed over a networked protocol such as [KeyGen2](#) (rather than locally), it is **recommended** alerting the user unless the key is having [AppUsage](#) = **encryption**

## pp\_deleteKey [50]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>TargetKeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Key management authorization signature
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**pp\_deleteKey** deletes a key created in an earlier provisioning session.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = **Authorization**

A conforming SKS **must** abort the provisioning session if **pp\_deleteKey** is mixed with other post provisioning operations referring to the same **TargetKeyHandle**.

Note that the *execution* of this method **must** be *deferred* to [closeProvisioningSession](#).

Regarding delete of PIN and PUK policy objects, see [Key Protection Objects](#).

*Continued on the next page...*

The following fragment shows how `pp_deleteKey` operations have been integrated in the [KeyGen2](#) protocol:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

<CertificatePath ... >
</CertificatePath>

<DeleteKey CertificateFingerprint="mNWEOLIAZrG ... dUg2aLA="
          ClientSessionID="_1292389cba4 ... 173d4334"
          ServerSessionID="_1292389cb8 ... c2ea36e"
          Authorization="ChPQRDT ... n/dJKrW3L"
          MAC="AvDWx6xbg3GDGzdz ... yJk8Js0Oul+Ba/Xc8="/>

</ProvisioningFinalizationRequest>
```

Before invoking `pp_deleteKey` the provisioning middleware needs to perform a number of steps:

1. Find the the *old* provisioning session associated with the `ClientSessionID` and `ServerSessionID` attributes of the `DeleteKey` element by calling [enumerateProvisioningSessions](#).
2. Find possible keys by calling [enumerateKeys](#) and ignoring all but those belonging to the provisioning session found in step #1.
3. For the set of keys found in step #2 call [getKeyAttributes](#) while looking for a key having an [End-Entity Certificate](#) matching the [SHA256 CertificateFingerprint](#).
4. If step #3 is successful `TargetKeyHandle` is recovered and `pp_deleteKey` can be invoked.

If any of these steps fail the provisioning session **must** be aborted. Also see [Remote Key Lookup](#).

## pp\_unlockKey [51]

### Input

Name	Type	Description
<b>ProvisioningHandle</b>	int	Local handle to an <i>open</i> provisioning session
<b>TargetKeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Key management authorization signature
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**pp\_unlockKey** works like [unlockKey](#) except that authorization is derived from a [Target Key Reference](#) instead of a PUK.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = **Authorization**

Note that the *execution* of this method **must** be *deferred* to [closeProvisioningSession](#) and that it **must** (internally) be performed in *advance* of any [pp\\_updateKey](#) or [pp\\_cloneKeyProtection](#) calls referring to the same **TargetKeyHandle**.

If the target key is associated with a PUK object the PUK error count **must** be cleared as well.

The following fragment shows how **pp\_unlockKey** operations have been integrated in the [KeyGen2](#) protocol:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
    ID="_0fa47ab3c00c ... a67992b6ac61c"
    MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

<CertificatePath ... >
</CertificatePath>

<UnlockKey CertificateFingerprint="mNWEOLIAZrG ... dUg2aLA="
    ClientSessionID="_1292389cba4 ... 173d4334"
    ServerSessionID="_1292389cb8 ... c2ea36e"
    Authorization="ChPQRDT ... n/dJKrW3L"
    MAC="AvDWx6xbg3GDGzdz ... yJk8Js0Oul+Ba/Xc8="/>

</ProvisioningFinalizationRequest>
```

Before invoking **pp\_unlockKey** the provisioning middleware needs to perform the same steps as for [pp\\_deleteKey](#).

## pp\_updateKey [52]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a <i>new</i> key belonging to an <i>open</i> provisioning session
<b>TargetKeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Key management authorization signature
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**pp\_updateKey** updates (replaces) a key created in an earlier provisioning session.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = [End-Entity Certificate](#) || **Authorization**

The new key **must** be *fully provisioned* (fitted with a certificate and optional attributes), *before* this method is called. However, the new key **must not** be PIN-protected since it supposed to *inherit* the old key's PIN protection scheme (if there is one). Inheritance does not mean “copying” but *linking* the new key to an existing PIN object. See [Key Protection Objects](#).

The target key and the new key **must** have identical [Key Application Usage](#).

Note that updating a key involves *all related data* (see [Key Entries](#)), with PIN protection as the only exception.

The **KeyHandle** of the updated key **must** after a successful update be set equal to **TargetKeyHandle**.

A conforming SKS **must** allow a (single) **pp\_updateKey** combined with an arbitrary number of [pp\\_cloneKeyProtection](#) calls referring to the same **TargetKeyHandle**.

Note that the *execution* of this method **must** be *deferred* to [closeProvisioningSession](#).

The following fragment shows how **pp\_updateKey** has been integrated in the [KeyGen2](#) protocol:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
                                ID="_0fa47ab3c00c ... a67992b6ac61c"
                                MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrM421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALGeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <UpdateKey CertificateFingerprint="mNWEOLIAZrG ... dUg2aLA="
              ClientSessionID="_1292389cba4 ... 173d4334"
              ServerSessionID="_1292389cb8 ... c2ea36e"
              Authorization="ChPQRDT ... n/dJKrW3L"
              MAC="AvDWx6xbg3GDGzdz ... yJk8Js0Oul+Ba/Xc8="/>
  </CertificatePath>

</ProvisioningFinalizationRequest>
```

Before invoking **pp\_updateKey** the provisioning middleware needs to perform the same steps as for [pp\\_deleteKey](#).

**KeyHandle** is the handle associated with **CertificatePath**.

# pp\_cloneKeyProtection [53]

## Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to a <i>new</i> key belonging to an <i>open</i> provisioning session
<b>TargetKeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Key management authorization signature
<b>MAC</b>	byte[32]	Vouches for the integrity and authenticity of the operation

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**pp\_cloneKeyProtection** clones the *protection scheme* of a key created in an earlier provisioning session and applies it to a newly created key.

The **MAC** uses the method described in [MAC Operations](#) where *Data* is arranged as follows:

*Data* = [End-Entity Certificate](#) || [Authorization](#)

The new key **must** be *fully provisioned* (fitted with a certificate and optional attributes), *before* this method is called. However, the new key **must not** be PIN-protected since it supposed to *inherit* the old key's PIN protection scheme (if there is one). Inheritance does not mean “copying” but *linking* the new key to an existing PIN object. See [Key Protection Objects](#).

The target key and the new key **must** have identical [Key Application Usage](#).

Note that an SKS **must not** allow inheritance of a custom PIN protection scheme with grouping **none** (see [PIN Grouping](#)).

A conforming SKS **must** allow multiple **pp\_cloneKeyProtection** calls referring to the same **TargetKeyHandle**.

Note that the *execution* of this method **must** be *deferred* to [closeProvisioningSession](#).

The following fragment shows how **pp\_cloneKeyProtection** has been integrated in the [KeyGen2](#) protocol:

```
<ProvisioningFinalizationRequest ClientSessionID="_126992b6 ... a8a6b484db8f"
    ID="_0fa47ab3c00c ... a67992b6ac61c"
    MAC="GcaqnRxW ... 8kabXDgWr=" Nonce="aqnPb6x0 ... kms34gfW2=" ... >

  <CertificatePath ID="Key.1" MAC="ngSgmRuPE ... HIFWrm421wY=">
    <ds:X509Data>
      <ds:X509Certificate>MIIC2TCCAcGgAwIBAgS ... NRT+VokJJsBecyALgeT0Dw==</ds:X509Certificate>
    </ds:X509Data>
    <CloneKeyProtection CertificateFingerprint="mNWEOLIAZrG ... dUg2aLA="
      ClientSessionID="_1292389cba4 ... 173d4334"
      ServerSessionID="_1292389cb8 ... c2ea36e"
      Authorization="ChPQRDT ... n/dJKrW3L"
      MAC="AvDWx6xbg3GDGzdz ... yJk8Js0Oul+Ba/Xc8="/>
  </CertificatePath>
</ProvisioningFinalizationRequest>
```

Before invoking **pp\_cloneKeyProtection** the provisioning middleware needs to perform the same steps as for [pp\\_deleteKey](#).

**KeyHandle** is the handle associated with **CertificatePath**.

## enumerateKeys [70]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Input enumeration handle

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>KeyHandle</b>	int	Output enumeration handle
<i>The following element <b>must</b> be set to zero if the output <b>KeyHandle</b> = 0</i>		
<b>ProvisioningHandle</b>	int	Handle to the associated provisioning session object

**enumerateKeys** enumerate keys for *closed* provisioning sessions. Closed provisioning session means that the key is ready for usage by *applications*.

The input **KeyHandle** **must** initially be set to 0 to start an enumeration round.

Succeeding calls **must** use the output **KeyHandle** as input to the next call.

When **enumerateKeys** returns with a **KeyHandle** = 0 there are no more key objects to read.

## getKeyAttributes [71]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>IsSymmetricKey</b>	bool	True if the active key is symmetric. See <a href="#">importSymmetricKey</a>
<b>PathLength</b>	byte	See <a href="#">setCertificatePath</a>
<b>X509Certificate...</b>	byte[]	
<b>AppUsage</b>	byte	See <a href="#">createKeyEntry</a>
<b>FriendlyName</b>	byte[]	
<b>EndorsedAlgorithms</b>	byte	
<b>EndorsedAlgorithm...</b>	uri	
<b>Extensions</b>	short	Number of <b>Type</b> URIs
<b>Type...</b>	uri	Extension <b>Type</b> URI. <i>Repeated</i> object
		See <a href="#">addExtension</a>

**getKeyAttributes** returns attribute data for provisioned keys.

For asymmetric keys the public key of the [End-Entity Certificate](#) signifies RSA or EC algorithm.

Also see [getKeyProtectionInfo](#).

## getKeyProtectionInfo [72]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>ProtectionStatus</b>	byte	See <a href="#">ProtectionStatus</a> table on the next page
<b>PUKFormat</b>	byte	Copy of <b>Format</b> defined by <a href="#">createPUKPolicy</a> [1]
<b>PUKRetryLimit</b>	short	Copy of <b>RetryLimit</b> defined by <a href="#">createPUKPolicy</a> [1]
<b>PUKErrorCount</b>	short	Current PUK error count for keys protected by a local PUK policy object [1]
<b>UserDefined</b>	bool	Copies of the corresponding <a href="#">createPINPolicy</a> parameters for keys protected by a local PIN policy object [1]
<b>UserModifiable</b>	bool	
<b>Format</b>	byte	
<b>RetryLimit</b>	short	
<b>Grouping</b>	byte	
<b>PatternRestrictions</b>	byte	
<b>MinLength</b>	short	
<b>MaxLength</b>	short	
<b>InputMethod</b>	byte	
<b>PINErrorCount</b>	short	Current PIN error count for keys protected by a local PIN policy object [1] See <a href="#">ProtectionStatus</a> table on the next page
<b>EnablePINCaching</b>	bool	Exact copies of the corresponding <a href="#">createKeyEntry</a> parameters
<b>BiometricProtection</b>	byte	
<b>ExportProtection</b>	byte	
<b>DeleteProtection</b>	byte	
<b>KeyBackup</b>	byte	Tells if there exists a <i>copy</i> of the key. See <a href="#">KeyBackup</a> table on the next page

**getKeyProtectionInfo** returns information about the protection scheme for a key including possible biometric options. In addition, the call retrieves the current protection status for the key.

Note 1: Fields **must** be set to zero if they do not apply to the key in question.

*Continued on the next page...*

The following table illustrates how the **ProtectionStatus** bit field should be interpreted:

Name	Value	Description
<b>PIN_PROTECTED</b>	0x01	The key is protected by a local PIN policy object
<b>PUK_PROTECTED</b>	0x02	The key is protected by a local PUK policy object. This bit <b>must</b> be <i>combined</i> with bit <b>PIN_PROTECTED</b>
<b>PIN_BLOCKED</b>	0x04	The key has locked-up due to PIN errors. This bit <b>must</b> be <i>combined</i> with bit <b>PIN_PROTECTED</b>
<b>PUK_BLOCKED</b>	0x08	The key has locked-up due to PUK errors. This bit <b>must</b> be <i>combined</i> with bit <b>PUK_PROTECTED</b>
<b>DEVICE_PIN</b>	0x10	The key is protected by a device PIN. Information about device PINs is out of scope for the SKS API. This bit <b>must</b> be the only active bit if applicable

If all bits are zero the key is not PIN protected.

The following table illustrates how the **KeyBackup** bit field should be interpreted:

Name	Value	Description
<b>SERVER</b>	0x01	The SERVER bit <b>must</b> be set if the key has been supplied through <a href="#">restorePrivateKey</a> or <a href="#">importSymmetricKey</a>
<b>LOCAL</b>	0x02	The LOCAL bit <b>must</b> be set if the key has been subject to an <a href="#">exportKey</a> operation

## getExtension [73]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Type</b>	uri	Type URI. See <a href="#">addExtension</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>SubType</b>	byte	Exact copies of the corresponding <a href="#">addExtension</a> parameters
<b>Qualifier</b>	byte[]	
<b>ExtensionData</b>	blob	

**getExtension** returns a typed extension object associated with a key.

Note that encrypted extensions are decrypted during provisioning.

If the extension is intended to be consumed by the SKS, **ExtensionData** **must** be returned as a zero-length array.

## setProperty [74]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Type</b>	uri	Type URI which <b>must</b> identify a <b>PropertyBag</b> extension. See <a href="#">addExtension</a>
<b>Name</b>	byte[]	<b>Property</b> name
<b>Value</b>	byte[]	<b>Property</b> value

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**setProperty** sets a **Property** in a **PropertyBag** linked to a key.

If the named **Property** does not exist or is not *writable*, an error **must** be returned.

## deleteKey [80]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Zero-length array, PIN, or PUK depending on <a href="#">Key Delete</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**deleteKey** removes a key from the [Credential Database](#).

If the key is the last belonging to a provisioning session, the session data objects are removed as well.

Invalid **Authorization** data to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

A conforming SKS **may** introduce physical presence methods like GPIO-based buttons, *circumventing* key [DeleteProtection](#) settings.

Regarding delete of PIN and PUK policy objects, see [Key Protection Objects](#).

## exportKey [81]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Zero-length array, PIN, or PUK depending on <a href="#">Key Export</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Key</b>	byte[]	Unencrypted key. For type information see <a href="#">getKeyAttributes</a>

**exportKey** exports a private or symmetric key from the [Credential Database](#).

Invalid **Authorization** data to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

Private (asymmetric) keys **must** be exported in [PKCS #8](#) format.

If a **non-exportable** key is referred to, **exportKey** **must** return [ERROR\\_NOT\\_ALLOWED](#) status.

Note that the [KeyBackup](#).**LOCAL** flag of the key **must** be set after execution of **exportKey**.

## unlockKey [82]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	PUK

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**unlockKey** re-enables a key that has been locked due to erroneous PIN entries.

Note that this method only applies to keys that are protected by local PIN and PUK policy objects.

Invalid **Authorization** data (PUK) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

If **unlockKey** succeeds all keys sharing the PIN object will be unlocked. See [PIN Grouping](#).

## changePIN [83]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	Original PIN
<b>NewPIN</b>	byte[]	The requested new PIN

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**changePIN** modifies a PIN for a key.

Note that the key **must** be protected by a local PIN policy object having the [UserModifiable](#) attribute set.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

If **changePIN** succeeds all keys sharing the PIN object will be updated. See [PIN Grouping](#).

## setPIN [84]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Authorization</b>	byte[]	PUK string
<b>NewPIN</b>	byte[]	The requested new PIN

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>

**setPIN** sets a PIN for a key *regardless of PIN block status* since it uses a PUK as authorization.

Note that the key **must** be protected by local PUK and PIN policy objects where the latter have the [UserModifiable](#) attribute set.

Invalid **Authorization** data (PUK) **must** return [ERROR\\_AUTHORIZATION](#) status.

If **setPIN** succeeds all keys sharing the PIN object will be updated and *unlocked*. See [PIN Grouping](#).

# signHashedData [100]

## Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Algorithm</b>	uri	Signature algorithm URI. See <a href="#">Asymmetric Key Signatures</a>
<b>Parameters</b>	byte[]	Parameters needed by some signature algorithms
<b>Authorization</b>	byte[]	Holds a PIN or is of zero length if no PIN is supplied
<b>Data</b>	byte[]	Hashed data to be signed. Also see <a href="#">CryptoDataSize</a>

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Result</b>	byte[]	Signed data including algorithm-specific padding

**signHashedData** performs an asymmetric key signature operation on the input **Data** object.

**Data** **must** be hashed *as required by the signature algorithm*.

The **Parameters** object **must** be of zero length for signature algorithms not needing additional input.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

The length of **Data** **must** match the hash algorithm. Note that signature algorithms that do not define a specific hash algorithm impose no tests on **Data** length. The `http://xmlns.webpki.org/keygen2/1.0#algorithm.rsa.none` signature algorithm **must** format the signature packet according to [PKCS #1](#) but without hash algorithm identifiers:

EMSA = 0x00 || 0x01 || PS || 0x00 || Data

# asymmetricKeyDecrypt [101]

## Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Algorithm</b>	uri	Encryption algorithm URI. See <a href="#">Asymmetric Key Encryption</a>
<b>Parameters</b>	byte[]	Parameters needed by some encryption algorithms
<b>Authorization</b>	byte[]	Holds a PIN or is of zero length if no PIN is supplied
<b>Data</b>	byte[]	Encrypted data

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Result</b>	byte[]	Decrypted data

**asymmetricKeyDecrypt** performs an asymmetric key decryption operation on the input **Data** object.

**Data** **must** be padded *as required by the encryption algorithm* like [PKCS #1](#) for [http://www.w3.org/2001/04/xmlenc#rsa-1\\_5](http://www.w3.org/2001/04/xmlenc#rsa-1_5).

The **Parameters** object **must** be of zero length for encryption algorithms not needing additional input.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

# keyAgreement [102]

## Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Algorithm</b>	uri	Key agreement algorithm URI. See <a href="#">Diffie-Hellman Key Agreement</a>
<b>Parameters</b>	byte[]	Parameters needed by some key agreement algorithms
<b>Authorization</b>	byte[]	Holds a PIN or is of zero length if no PIN is supplied
<b>PublicKey</b>	byte[]	The other party's public key

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Result</b>	byte[]	Shared secret

**keyAgreement** performs an asymmetric key agreement operation resulting in a shared secret.

**PublicKey** **must** be an EC public key in [X.509](#) DER format using the same curve as **KeyHandle**. See [Elliptic Curves](#).

The **Parameters** object **must** be of zero length for key agreement algorithms not needing additional input.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

## performHMAC [103]

### Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Algorithm</b>	uri	HMAC algorithm URI. See <a href="#">HMAC Operations</a>
<b>Authorization</b>	byte[]	Holds a PIN or is of zero length if no PIN is supplied
<b>Data</b>	blob	Data to be HMACed. Also see <a href="#">CryptoDataSize</a>

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Result</b>	byte[]	HMACed data

**performHMAC** performs a symmetric key HMAC operation on the input **Data** object.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

# symmetricKeyEncrypt [104]

## Input

Name	Type	Description
<b>KeyHandle</b>	int	Local handle to the target key
<b>Algorithm</b>	uri	Encryption algorithm URI. See <a href="#">Symmetric Key Encryption</a>
<b>Mode</b>	bool	True for encryption, false for decryption
<b>IV</b>	byte[]	Initialization Vector. Zero length for the <a href="#">XML Encryption</a> algorithms
<b>Authorization</b>	byte[]	Holds a PIN or is of zero length if no PIN is supplied
<b>Data</b>	blob	Data to be encrypted or decrypted. Also see <a href="#">CryptoDataSize</a>

## Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>Result</b>	blob	Encrypted or decrypted data

**symmetricKeyEncrypt** performs a symmetric key encryption or decryption operation on the input **Data** object.

Note that if an **IV** (Initialization Vector) is not required by the encryption algorithm, **IV** **must** be of zero length.

Invalid **Authorization** data (PIN) to the key **must** return [ERROR\\_AUTHORIZATION](#) status.

## updateFirmware [110]

### Input

Name	Type	Description
<b>Chunk</b>	blob	Firmware code chunk

### Output

Name	Type	Description
<b>Status</b>	byte	See <a href="#">Return Values</a>
<b>NextURL</b>	uri	Next URL or zero-length string

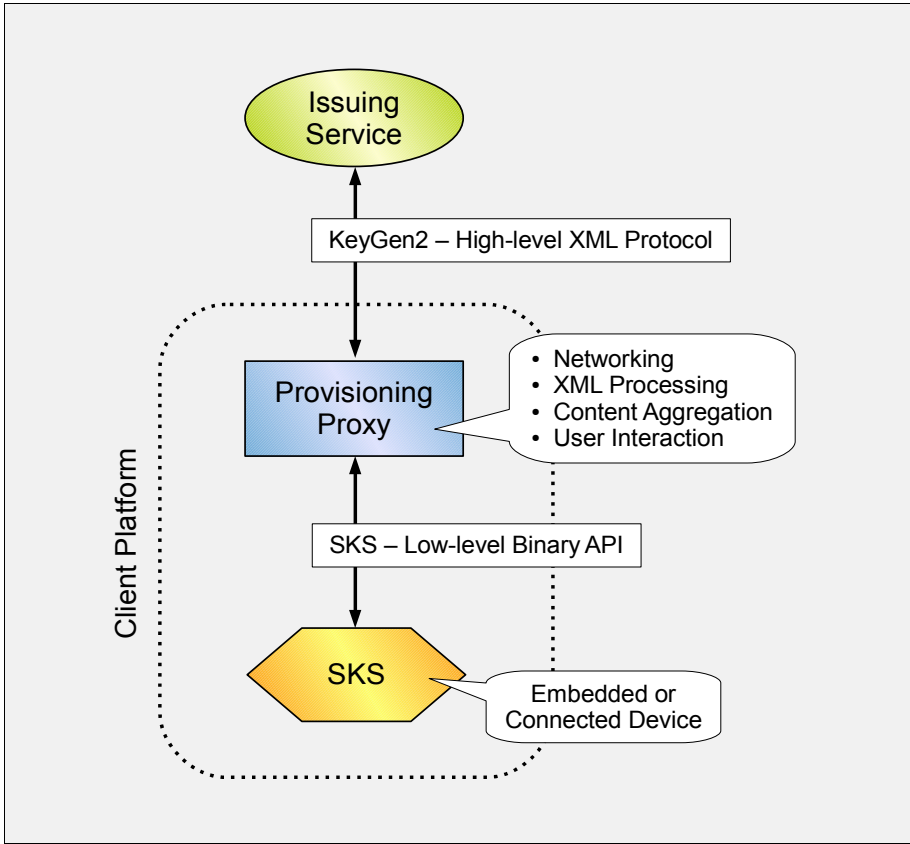

**updateFirmware** is an *optional* method that performs a firmware update operation. The method is only available if the [UpdateURL](#) is non-zero. To perform an update, the SKS management system issues an HTTP GET operation to the service pointed out by [UpdateURL](#). If the service returns a content of zero length, the SKS device is assumed to be up-to-date, else **updateFirmware** should be called with the content in **Chunk**. The return value from the call is either a new URL to be used analogous to [UpdateURL](#), or a zero-length string indicating that the update is ready.

A conforming update service **must** use the MIME-type **application/octet-stream**.

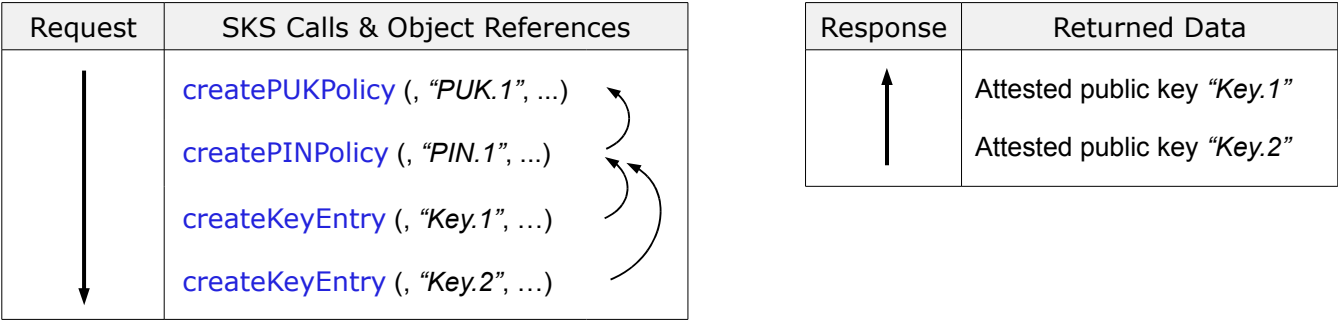

The **updateFirmware** method **must** be implemented in such a way that the SKS container cannot be made inoperable due to network errors or aborted update operations. In addition, the SKS container **must** be able to *securely authenticate* the update service's **Chunk** data

# Appendix A. KeyGen2 Proxy

SKS departs from most other SE (Security Element) designs by relying on a “Semi-Trusted Proxy” for the provisioning and management of keys. Introducing a proxy in a scheme which is claimed supporting *true end-to-security* may sound like a contradiction. However, any alterations to the data flowing between the two end-points (the issuing service and the SKS) will be detected by one of them due to the use of *stateful sessions*, *sequence counters* and *MAC operations*. The picture below shows the SKS/KeyGen2 provisioning architecture:

Since SKS methods *by design* are low-level, most of the comparatively high-level provisioning operations result in multiple SKS calls. In addition, there is a need for referencing objects created by preceeding calls. As it would be quite inefficient if every call forced a network “roundtrip”, a core proxy task is *aggregating and linking SKS calls and return data*. This is facilitated through the SKS virtual namespace concept which relieves issuers from ever dealing with raw (and device-dependent) object handles or worrying about name collisions. See [Object IDs](#). The following graph outlines content aggregation and linking when applied to the KeyGen2 example on page 34:

Another provisioning activity orchestrated by the proxy is requesting (and validating according to the issuer's policy), user-defined PINs, because SKS depends on that all initial PIN values are set during key entry creation.

## Appendix B. Sample Session

The following provisioning sample session shows the *sequence* for creating an X.509 certificate with a matching PIN and PUK protected private key:

```
ProvisioningHandle, ... = createProvisioningSession (...)  
PUKPolicyHandle = createPUKPolicy (ProvisioningHandle, ...)  
PINPolicyHandle = createPINPolicy (ProvisioningHandle, ... , PUKPolicyHandle, ...)  
KeyHandle, ... = createKeyEntry (ProvisioningHandle, ... , PINPolicyHandle, ...)  
  
    External certification of the generated public key happens here...  
  
setCertificatePath (KeyHandle, ...)  
closeProvisioningSession (ProvisioningHandle, ...)
```

Note that **Handle** variables are only used by local middleware, while (not shown) variables like **SessionKey**, **MAC**, **ID**, etc. are primarily used in the communication between an issuer and the SKS.

If keys are to be created entirely locally, this requires local software emulation of an issuer.

## Appendix C. Reference Implementation

To further guide implementers, an open source SKS reference implementation in java® is available including a JUnit suite.

URL: <http://code.google.com/p/openkeystore>

## Appendix D. Remote Key Lookup

In order to update keys and related data, SKS supports post provisioning operations like `pp_deleteKey` where issuers are securely shielded from each other by the use of a `KeyManagementKey`.

However, depending on the use-case, an issuer may need to get a list of applicable keys, *before* launching post provisioning operations. Such a facility is available in `KeyGen2` as illustrated by the XML fragment below:

```
<CredentialDiscoveryRequest ... >

  <LookupSpecifier ID="Lookup.1" Nonce="nSgmg4cznqE ... WrH2421w9SYA=">
    <SearchFilter Email="john.doe@example.com"/>
    <ds:Signature>
      <ds:SignedInfo>
        <ds:CanonicalizationMethod Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
        <ds:SignatureMethod Algorithm="http://www.w3.org/2001/04/xmldsig-more#rsa-sha256" />
        <ds:Reference URI="#Lookup.1">
          <ds:Transforms>
            <ds:Transform Algorithm="http://www.w3.org/2000/09/xmldsig#enveloped-signature" />
            <ds:Transform Algorithm="http://www.w3.org/2001/10/xml-exc-c14n#" />
          </ds:Transforms>
          <ds:DigestMethod Algorithm="http://www.w3.org/2001/04/xmlenc#sha256" />
          <ds:DigestValue>JBfoi8iBKRYWxXYITTU1cdyybMTyJr+WDW+qCJdxoGE=</ds:DigestValue>
        </ds:Reference>
      </ds:SignedInfo>
      <ds:SignatureValue>mSMaH6wChPQRDT... JKrW3n/dL7seGbg==</ds:SignatureValue>
    </ds:Signature>
    <ds:KeyInfo>
      <ds:RSAKeyValue>
        <ds:Modulus>ALhBpUjJK/mSjPAe/ ... fXG8z1V3mVDZTBM7eZ</ds:Modulus>
        <ds:Exponent>AQAB</ds:Exponent>
      </ds:RSAKeyValue>
    </ds:KeyInfo>
  </ds:Signature>
</LookupSpecifier>

</CredentialDiscoveryRequest>
```

The example works as follows:

1. Verify that the **Signature** is *technically* valid. Note that the actual issuer is *ignored* since an SKS has no opinion about what issuers are trustworthy or not.
2. Verify that the freshness **Nonce** matches **SHA256** (`ClientSessionID || ServerSessionID`). See `createProvisioningSession` and `Data Types`.
3. Enumerate all sessions having a `KeyManagementKey` matching the public key of the **Signature**. This serves as an *Issuer Filter*. See `enumerateProvisioningSessions`.
4. From step #3 enumerate all matching SKS keys and related certificates. See `enumerateKeys` and `getKeyAttributes`.
5. Collect the keys from step #4 that also feature the e-mail addresss "`john.doe@example.com`" in the **End-Entity Certificate**.

The result is sent back to the issuer in the form of a list of **SHA256 (End-Entity Certificate)** fingerprints and session IDs.

Remote key lookups are performed at the *middleware level* since they are passive, XML intensive, and do not access private or secret keys. The primary purpose with credential lookups is *improving provisioning robustness*, while the *Issuer Filter* protects user privacy by constraining lookup data to the party to where it belongs.

## Appendix E. Security Considerations

Note: The following section only *partially* applies to the [Privacy Enabled Provisioning](#) mode.

This document does not cover the *physical* security of the key-store since SKS does not differ from other schemes in this respect.

However, the provisioning concept has some specific security characteristics. One of the most critical operations in SKS is the creation of a shared [SessionKey](#) because if such a key is intercepted or guessed by an attacker, the integrity of the entire session is potentially jeopardized.

If you take a peek at [createProvisioningSession](#) you will note that the [SessionKey](#) depends on issuer-generated and SKS-generated ephemeral public keys. It is pretty obvious that malicious middleware could replace such a key with one it has the private key to and the issuer wouldn't notice the difference. This is where the attestation signature comes in because it is computationally infeasible creating a matching signature since the both of the ephemeral public keys are enclosed as a part of the signed attestation object. That is, the issuer can when receiving the response to the provisioning session request, easily detect if it has been manipulated and *cease the rest of the operation*.

As earlier noted, the randomness of the [SessionKey](#) is crucial for all provisioning operations.

Missing or repeated objects are indirectly monitored by the use of [MACSequenceCounter](#), while the SKS “book-keeping” functions will detect other possible irregularities during [closeProvisioningSession](#). This means that an issuer **should not** consider issued credentials as valid unless it has received a successful response from [closeProvisioningSession](#).

The [SessionKeyLimit](#) attribute defined in [createProvisioningSession](#) is another security measure which aims to limit exhaustive attacks on the [SessionKey](#).

For algorithms that are considered as vulnerable to brute-force key searches, a simple workaround is adding a short *initial delay* to the applicable [User API](#) method. Since SKS is exclusively intended for user authentication a 1-100 ms delay imposes a (from the user's point of view), *hardly noticeable* impact on the performance.

By using the [EndorsedAlgorithm](#) option, issuers can specify exactly which algorithms that are permitted for a given key.

A significant feature of SKS is that it is identified by a digital certificate, preferably issued by a known vendor of trusted hardware. This enables the issuer to securely identify the key-container both from a cryptographic point of view (brand, type etc) and as a specific unit. The latter also makes it possible to communicate the container identity as an SHA1 fingerprint of the [Device Certificate](#) which facilitates novel and secure enrollment procedures, *typically eliminating the traditional sign-up password*.

That any issuer (after the user's consent), can provision keys may appear a bit scary but *keys do not constitute of executable code* making it less interesting in tricking users accepting “bad” issuers. In addition, the provisioning middleware is also able to validate incoming data for “sanity” and even abort unreasonable requests, such as asking for 10 keys or more to be created.

Although not a part of SKS, [KeyGen2](#) puts a signature derived from the [SessionKey](#) over the provisioning session response. The latter holds an HTTPS [ServerCertificateFingerprint](#) giving the issuer an opportunity verifying that there actually is a “straight line” between the client and server.

One might suspect that the [VSD](#) scheme by relying on a static, *potentially issuance-wide* [KeyManagementKey](#) could introduce client-side vulnerabilities but that is unlikely to be the case: If a key management signature is intercepted by an attacker, the inclusion of a high entropy [SessionKey](#) and the [Device Certificate](#) renders it useless in another session or device. It is also worth noting that the post provisioning operations *by design* do not expose secret or private key data.

There is no protection against DoS (Denial of Service) attacks on SKS storage space due to malicious middleware.

SKS does not have any built-in policy, it is up to the individual *issuer* deciding about suitable key protections options, key sizes, and private key imports.

## Appendix F. Intellectual Property Rights

This document contains several constructs that *could* be patentable but the author has no such interests and therefore puts the entire design in *public domain* allowing anybody to use all or parts of it at their discretion. In case you adopt something you found useful in this specification, feel free mentioning where you got it from ☺

Note: it is possible that there are pieces that already are patented by *other parties* but the author is currently unaware of any IPR encumbrances.

Some of the core concepts have been submitted to <http://defensivepublications.org> and subsequently been published in IP.COM's *prior art database*.

## Appendix H. Acknowledgments

SKS and KeyGen2 heavily build on schemes pioneered by other individuals and organizations, most notably:

- *CT-KIP by RSA Security*: KeyGen2 format and basic operation
- *ObC by Nokia*: Key management through dynamic deployment of issuer-specific symmetric keys ([VSD](#)), and support for keys bound to downloaded data (in ObC code)
- *SCP80 by GlobalPlatform*: Secure messaging including “rolling MACs”
- *CertEnroll by Microsoft*: Processes

There is also a bunch of individuals that have been instrumental for the creation of SKS. I need to check who would accept to be mentioned :-)

KeyGen2 is an “homage” to Netscape Communications Corp. who created the first on-line provisioning system called KeyGen.

[anders.rundgren@telia.com](mailto:anders.rundgren@telia.com)

## Appendix J. To Do List

Although it would be nice to say “it is 100% ready” there are still a few things missing:

- Investigating “physical presence” GPIO options
- Language check
- Filling in the references
